13. SUPPLEMENTARY NOTES

14. ABSTRACT
The U.S. Army Research Laboratory Dismounted Infantry Simulator has been updated for Synthetic Environment Data Representation and Interchange Specification (SEDRIS) 3.1.1 transmittal generation. Specifically, the SEDRIS 3.0.3 write application for a munition/structure interaction, as computed by DISim, is now compliant with the 3.1.1 specification. SEDRIS defines a comprehensive standard for the representation and distribution of environmental data. Our initial effort only involved two of the five components of the SEDRIS technology—the Data Representation Model and the Application Programming Interface. The other three components will be added directly, if needed, since translation would not be necessary. It is our intent to not only present a unique solution but to also identify potential areas of concern for a general 3.0.3 to 3.1.1 migration.

1. Introduction

The U.S. Army Research Laboratory (ARL) Dismounted Infantry Simulator (DISim) is a training system for military operations on urban terrain (*1*). One particular application of DISim is the real-time computation and display of an urban structure fractured by a munition (*2*) and subsequent distribution of resultant rubble (*3*). The DISim approximation is empirically based, taking into account only the geometry of the situation; but a physical solution is being considered when real-time display is not compromised. An example of its utility could be when a soldier affixes an explosive on a building and then detonates it for tactical entry to the building interior. Simulation of such a perforation is computed by the DISim Hole Library, which is written in the object-oriented language C++. The resultant geometry and corresponding attribute data for the effected structure(s) are placed in Synthetic Environment Data Representation and Interchange Specification (SEDRIS) transmittal(s); the C++ language bindings of the application programming interface (API) are used for transmittal generation. SEDRIS transmittal formatted (STF) data is then available to compliant read APIs on a network of computers.

ARL recently decided to update DISim for the latest SEDRIS technology (from 3.0.3 to 3.1.1), after several suggestions from the SEDRIS mailing list. Many on that list, which is primarily monitored by SEDRIS associates, believe 3.1.1 is not only more stable but also offers a much more consistent interface. Their web site (*4*) provides both guidance and software to promote migration. This includes a Perl script for global string replacement with exact matching. There are restrictions, however, when running the name_change.pl script as documented by a README file at the same web site. Still our application had to be manually edited for full 3.1.1 compliancy.

It is our hope that this report will assist in 3.0.3 to 3.1.1 migration of SEDRIS applications. We only address the Data Representation Model and the API for interchange of the environmental data. Our application did not use the other components—namely, the Spatial Reference Model, the Environmental Data Coding Specification, and the STF. Those who are just learning SEDRIS may want to go directly to the 3.1.1 specification.

2. Migration of STF_Fracture

Appendix A depicts the format of an STF_Fracture transmittal. The actual C++ class for the 3.0.3 write API (Appendix B) has been modified for 3.1.1 transmittal generation (Appendix C). Both versions are included in the appendices for a line-by-line comparison. The overall design of the class has stayed the same, but the representation (member data) and the interface (member

functions) had to be changed. Data types, class fields, and constants were either renamed or removed as necessary.

The STF_Fracture interface has been divided into three tables. Table 1 consists of methods for instantiating an STF_Fracture object, including the transmittal root and the following top-level objects: description, point of contact, access, data quality, keywords, absolute time point, citation, rocess, and transmittal summary. All text strings, which are simply defined as a sequence of ASCII characters, were updated as shown. Sometimes this was an entire class name (e.g., SE_OBJECT renamed to SE_Object), and other times only the field name had to be changed (e.g., string_value renamed to characters). Table 2 lists string values that were changed when constructing containers of geometric and attribute data. Each geometric primitive, which is a triangle in our simulation environment, has a mapping function pointing to data in the image library. The addImage() method in Table 3 is needed for placing texture data in this library. Note that multiple occurrences of identical replacements are not repeated in successive tables. This was done to minimize entries in these three tables.

Table 1. Transmittal root and top level objects of STF_Fracture.

Method Name	3.0.3 String	3.1.1 String
create()	SE_CREATE SE_SUCCESS	SE_AC_MODE_CREATE SE_STAT_CODE_SUCCESS
createDescription()	SE_OBJECT SE_FIELDS SE_TRANSMITTAL_ROOT_TOKEN string_length string_value SE_SUCCESS SE_DESCRIPTION_TOKEN SE_POINT_OF_CONTACT_TOKEN SE_ACCESS_TOKEN SE_DATA_QUALITY_TOKEN SE_KEYWORDS_TOKEN SE_ABSOLUTE_TIME_POINT_TOKEN SE_CITATION_TOKEN SE_PROCESS_TOKEN SE_TRANSMITTAL_SUMMARY_TOKEN	SE_Object SE_Fields SE_DRM_CLS_TRANSMITTAL_ROOT length characters SE_STAT_CODE_SUCCESS SE_DRM_CLS_DESCRIPTION SE_DRM_CLS_POINT_OF_CONTACT SE_DRM_CLS_ACCESS SE_DRM_CLS_DATA_QUALITY SE_DRM_CLS_KEYWORDS SE_DRM_CLS_ABSOLUTE_TIME_POINT SE_DRM_CLS_CITATION SE_DRM_CLS_PROCESS SE_DRM_CLS_TRANSMITTAL_SUMMARY

The approach taken was to examine the core header file sedris.h for actual changes to the API. Although this may not have been the most efficient approach for simple changes, it did result in a better understanding of the new definition. The alternative is using the previously mentioned script.

The application programmer will probably have little difficulty in strict string replacement for a particular case. However, actual logic changes require a more thorough understanding of SEDRIS technology. In our particular application, there were two main areas of concern. First, it was determined that the SE_AddToTransmittal() function had to be removed in 3.1.1. This

impacted lines 56–59 of the original STF_Fracture.C (Appendix B). The operation is now absorbed when the object is created.

Also, the 3.1.1 specification states that the implementation identifier argument of SE_CreateObject() needs to be replaced by the SE_Transmittal pointer. Secondly, two fields of the image mapping function were removed—the id and presentation_domain fields. SEDRIS 3.1.1 guides state that this can be done safely.

3. Conclusion and Future Efforts

This report presented details for translating the STF_Fracture class of DISim from SEDRIS 3.0.3 to a 3.1.1 implementation. The exact string replacements were given in the three tables. In addition, logic changes were identified, and appropriate methods were modified.

We are now in the process of validating the generated transmittals for full compliancy. "Side-by-Side" (SbS) by Acusoft, Inc., will be used for graphical display of resultant transmittals (*5*). However, the latest version (SbS 2.5) must be used to view 3.1.1 transmittals.

Future research will include the evaluation of existing technologies for synthetic environment representation in a Web environment. Possibilities are extensible markup language applications, such as extensible 3D (X3D), and the extensible modeling and simulation framework (XMSF), which allows for easy interaction over a highly distributed network. SEDRIS provides a thorough description of synthetic environments, but simulators on a network must have a read API to understand these transmittals. While XMSF may not be a replacement for SEDRIS, it could provide an extension for easier interoperation of simulation applications.

Appendix A. Tree Representation of STF_Fracture Transmittal

The following diagram organizes a Synthetic Environment Data Representation and Interchange Specification (SEDRIS) transmittal in hierarchical format. A SEDRIS transmittal is generated for each munition/structure fracture in the Dismounted Infantry Simulator.

STF_Fracture Transmittal

Appendix B. 3.0.3 STF_Fracture Class

The C++ class STF_Fracture encapsulates both data and functions for a Synthetic Environment Data Representation and Interchange Specification 3.0.3 transmittal of a Dismounted Infantry Simulator fracture. The member data and method interfaces are given in the header file STF_Fracture.H; methods are subsequently defined in the source file STF_Fracture.C. Note that a default constructor and destructor are also defined in STF_Fracture.H.

Appendix C. 3.1.1 STF_Fracture Class

The C++ class for Synthetic Environment Data Representation and Interchange Specification 3.1.1 transmittal generation of urban structure fracture is now given. This class is similiar to that in Appendix B but differs due to 3.1.1 requirements.

The following pages in this appendix appear in their original form, without editorial change.

```
/* ============================================================================================== */
/*                                                                                                */
