16. Abstract <p>A database of incremental cumulative-rainfall values for storms that occurred in urban and small rural watersheds in north and south central Texas during the period 1959 to 1986 was used to develop empirical, dimensionless, cumulative-rainfall hyetographs. Storm-quartile classifications were determined from the cumulative-rainfall values, which were divided into data groups on the basis of storm-quartile classification (first, second, third, fourth, and first through fourth combined), storm duration (0 to 6, 6 to 12, 12 to 24, 24 to 72, and 0 to 72 hours), and rainfall amount (1 inch or more). Removal of long leading tails, in effect, shortened the storm duration and, in some cases, affected the storm-quartile classification. Therefore, two storm groups, untrimmed and trimmed, were used for analysis. The trimmed storms generally are preferred for interpretation. For a 12-hour or less trimmed storm duration, approximately 49 percent of the storms are first quartile. For trimmed storm durations of 12 to 24 and 24 to 72 hours, 47 and 38 percent, respectively, of the storms are first quartile. For a trimmed storm duration of 0 to 72 hours, the first-, second-, third-, and fourth-quartile storms accounted for 46, 21, 20, and 13 percent of all storms, respectively.</p> <p>The 90th-percentile curve for first-quartile storms indicated about 90 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 10th-percentile curve for first-quartile storms indicated about 30 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 90th-percentile curve for fourth-quartile storms indicated about 33 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 10th-percentile curve for fourth-quartile storms indicated less than 5 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration.</p> <p>Statistics for the empirical, dimensionless, cumulative-rainfall hyetographs are presented in the report along with hyetograph curves and tables. The curves and tables presented do not present exact mathematical relations but can be used to estimate distributions of rainfall with time for small drainage areas of less than about 160 square miles in urban and small rural watersheds north and south central in Texas.</p>

## **Abstract**

A database of incremental cumulative-rainfall values for storms that occurred in small urban and rural watersheds in north and south central Texas during the period from 1959 to 1986 was used to develop empirical, dimensionless, cumulative-rainfall hyetographs. Storm-quartile classifications were determined from the cumulative-rainfall values, which were divided into data groups on the basis of storm-quartile classification (first, second, third, fourth, and first through fourth combined), storm duration (0 to 6, 6 to 12, 12 to 24, 24 to 72, and 0 to 72 hours), and rainfall amount (1 inch or more). Removal of long leading tails, in effect, shortened the storm duration and, in some cases, affected the storm-quartile classification. Therefore, two storm groups, untrimmed and trimmed, were used for analysis. The trimmed storms generally are preferred for interpretation. For a 12-hour or less trimmed storm duration, approximately 49 percent of the storms are first quartile. For trimmed storm durations of 12 to 24 and 24 to 72 hours, 47 and 38 percent, respectively, of the storms are first quartile. For a trimmed storm duration of 0 to 72 hours, the first-, second-, third-, and fourth-quartile storms accounted for 46, 21, 20, and 13 percent of all storms, respectively.

The 90th-percentile curve for first-quartile storms indicated about 90 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 10th-percentile curve for first-quartile storms indicated about 30 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 90th-percentile curve for fourth-quartile

storms indicated about 33 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 10th-percentile curve for fourth-quartile storms indicated less than 5 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration.

Statistics for the empirical, dimensionless, cumulative-rainfall hyetographs are presented in the report along with hyetograph curves and tables. The curves and tables presented do not present exact mathematical relations but can be used to estimate distributions of rainfall with time for small drainage areas of less than about 160 square miles in urban and small rural watersheds in north and south central Texas.

## **Introduction**

Knowledge of the distribution of rainfall with time is important for addressing hydrologic problems such as the design of culverts for small rural watersheds and the design of urban storm-sewer systems. This knowledge also is useful for studying soil erosion, studying the flood potential of various types of rainfall events, and advancing the general understanding of the physics of the atmosphere with regard to precipitation processes (Huff, 1967). To obtain knowledge about the distribution of rainfall in Texas, synthetic distributions presently (2003) are constructed using rainfall hyetographs by the Soil Conservation Service (1973). These hyetographs, which are graphical representations of rainfall with time, are an important element of numerous hydraulic designs throughout Texas and are used in conjunction with unit hydrographs (Chow and others, 1988; Haan and others, 1994) to obtain peak-discharge estimates and hydrograph shapes used for hydraulic design applications. An increase in the reliability of peak-discharge estimates can help engineers and others develop more cost-effective drainage designs.

## 2 Empirical, Dimensionless, Cumulative-Rainfall Hyetographs for Selected Small Watersheds in Texas

To determine if the rainfall hyetographs (Soil Conservation Service, 1973) presently used by the Texas Department of Transportation (TxDOT) are representative of Texas storms and to provide a new procedure to develop hyetographs if the present hyetographs are not representative, the U.S. Geological Survey (USGS) in 2000, in cooperation with TxDOT and in collaboration with Texas Tech University, the University of Houston, and Lamar University, began a multicomponent study of the characteristics of rainfall in Texas. The purpose of this study, which is part of the larger multicomponent study, was to develop empirical, dimensionless, cumulative-rainfall hyetographs using procedures similar to those given by Huff (1967, 1990). Storm-quartile classifications were determined from cumulative-rainfall values for small watersheds in Texas. The cumulative-rainfall values then were divided into data groups based upon storm quartiles, storm durations, and rainfall totals of 1 inch or more. This report presents the empirical, dimensionless, cumulative-rainfall hyetographs developed during the study.

## Database

The database used for this study was developed from ongoing, collaborative, rainfall-runoff research projects

sponsored by TxDOT and the USGS. The ongoing research projects are being conducted by Texas Tech University, the University of Houston, Lamar University, and the USGS. The database includes incremental cumulative-rainfall values for 1,659 runoff-producing storms that occurred during the period from 1959 to 1986 at or proximate to 91 USGS streamflow-gaging stations located in small urban and rural watersheds in north and south central Texas (fig. 1). Descriptive information for the streamflow-gaging stations is given in supplement 1.

Rainfall-gaging stations (precipitation gages) represented in the database were located around the urban areas of Austin, Dallas, Fort Worth, and San Antonio, Tex., and in rural areas within the Brazos, Colorado, San Antonio, and Trinity River Basins. Storm durations ranged from a few hours to several days, and cumulative-rainfall amounts ranged from less than 1 inch to more than 10 inches. These rainfall amounts were assumed to be representative of rainfall amounts across the drainage area of the coinciding streamflow-gaging station. Drainage areas for the 91 streamflow-gaging stations ranged from 0.26 to 166 square miles; however, drainage areas for 72 of the stations were less than 20 square miles (supplement 1) (Asquith and others, 2004). For drainage areas that had more than one precipitation gage, an accumulated weighted-precipitation amount was derived from the multiple precipitation gages

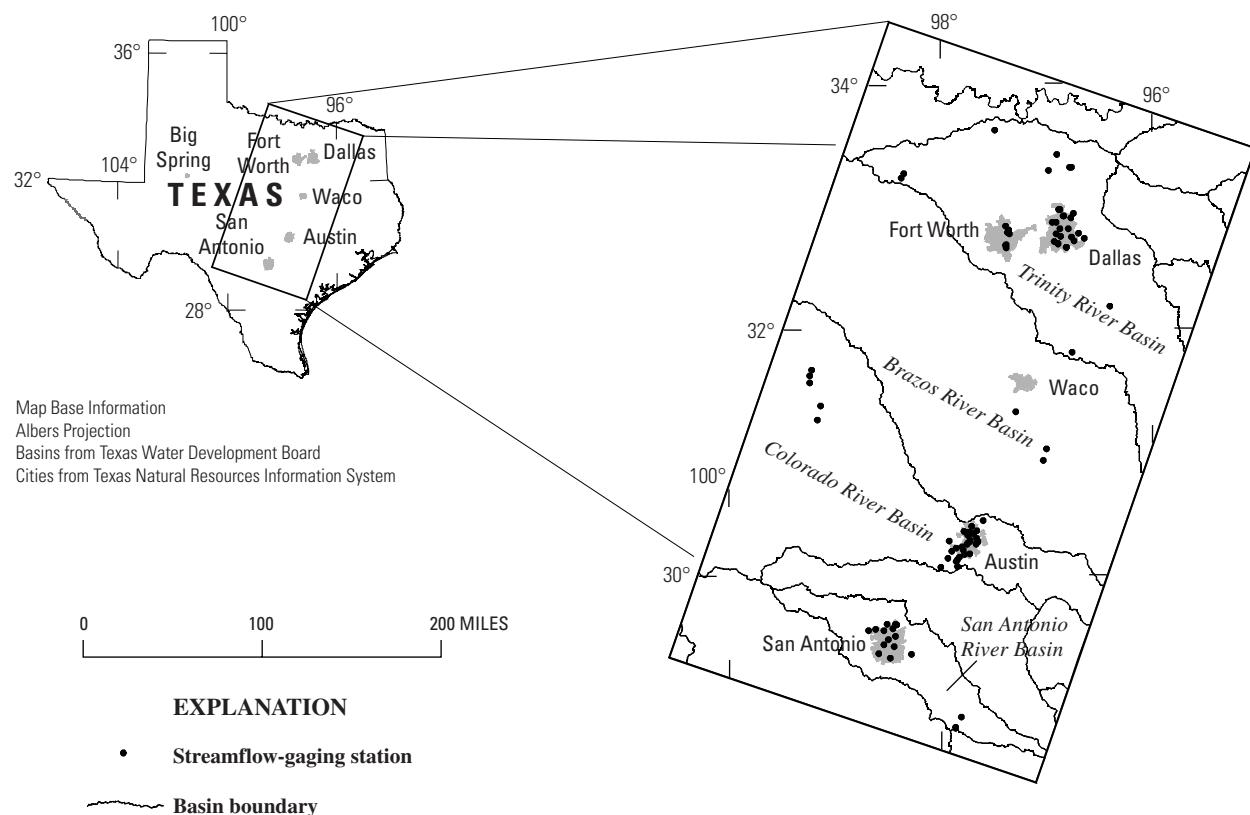

Figure 1. Locations of streamflow-gaging stations represented in hyetograph database. (From Asquith and others, 2003.)

and was considered to be the best estimate of rainfall for that drainage area. The accumulated weighted-precipitation estimates were areal rainfall values rather than point rainfall values. For stations that had only one precipitation gage, the values were point values. The precipitation data used for this study are on file at the USGS office in Bismarck, N. Dak. Detailed discussions of the database used and locations of the precipitation gages are given in Asquith (2003), Asquith and others (2003), Asquith and Thompson (2003), and Asquith and others (2004).

## Previous Hyetograph Research

Previous hyetograph research was conducted by Huff (1967, 1990), the Soil Conservation Service (1973), Pani and Haragan (1981), and Asquith (2003). Most of the following discussion was adapted from Asquith (2003).

### Research by Huff

Huff (1990) presented dimensionless rainfall hyetographs as families of curves that were derived for storms classified as first, second, third, or fourth quartile. The storms were classified by Huff (1967) according to whether the greatest percentage of cumulative rainfall occurred in the first, second, third, or fourth quarter of the storm duration. Huff (1967) defined a "storm" as a "rain period separated from preceding and succeeding rainfall by 6 hours or more." The database used by Huff (1967) includes data for 261 storms that occurred over a

400-square-mile network encompassing 49 recording rain gages in east-central Illinois. Data given in the database were collected between 1955 and 1966. All storms used had an areal mean rainfall of at least 0.5 inch and a duration of 3 to 48 hours. Also, at least one rain gage within the storm area had recorded at least 1 inch of rainfall during the storm duration.

In Huff (1967), the relative frequencies of the storms were 30, 36, 19, and 15 percent for the first, second, third, and fourth quartiles, respectively. These frequencies were slightly different in Huff (1990) because the differences between point rainfall and areal rainfall were considered for that study. Huff (1990) concluded that first-quartile storms often had durations of less than 6 hours, second-quartile storms often had durations of 6 to 12 hours, third-quartile storms often had durations of 12 to 24 hours, and fourth-quartile storms often had durations of more than 24 hours.

The median (50th-percentile) dimensionless hyetograph curves presented by Huff (1990) and shown in figure 2 were derived from point rainfall values (that is, rainfall data specifically for the recording device). The curves presented by Huff (1990) and shown in figure 3 were derived from areal rainfall values for areas that ranged from 10 to 50 square miles. Huff (1990) also provided curves that enveloped the median curve and represented other percentiles that ranged from 10 to 90 percent. A comparison of the corresponding curves in figures 2 and 3 indicated the difference between the curves derived from point rainfall values and the curves derived from areal rainfall values generally was small. Huff (1990) concluded that the curves derived from point rainfall values also are

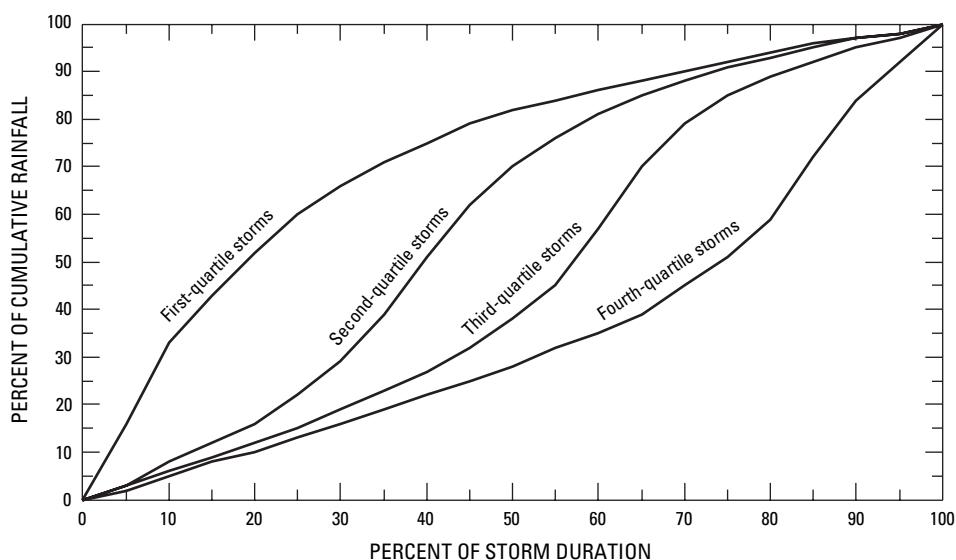

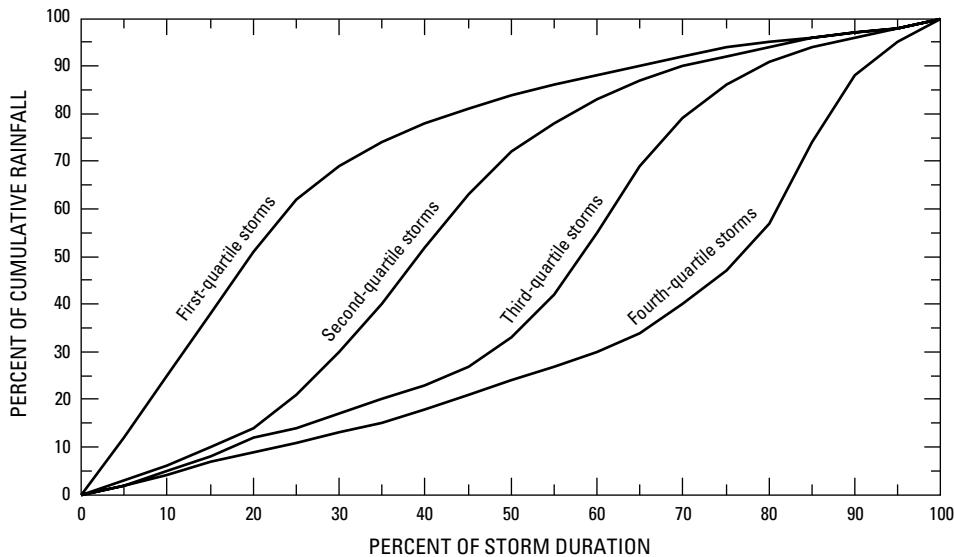

Figure 2. Median (50th-percentile) dimensionless hyetograph curves derived from point rainfall values. (Modified from Huff, 1990.)

#### 4 Empirical, Dimensionless, Cumulative-Rainfall Hyetographs for Selected Small Watersheds in Texas

**Figure 3.** Median (50th-percentile) dimensionless hyetograph curves derived from areal rainfall values. (Rainfall values are for areas that ranged from 10 to 50 square miles.) (Modified from Huff, 1990.)

valid for areas but that the validity of the curves diminishes as the area increases.

A discussion on the analysis of rainfall bursts and the effects of rainfall type, storm type, and storm shape and orientation on the distribution of rainfall with time is given in Huff (1967). Huff (1990) concluded that, for hydraulic design applications, first-quartile storm hyetographs should be used for time scales of about 6 hours or less, and second-quartile storm hyetographs should be used for time scales of about 6 to 12 hours. Third- and fourth-quartile storm hyetographs were not discussed for design applications.

#### Research by the Soil Conservation Service

The approach used by the Soil Conservation Service (1973), now the Natural Resources Conservation Service, provides dimensionless hyetograph curves classified into four types dependent upon specific regions. The Type II and III curves represent storms in Texas and elsewhere in the United States. The Type II curves are applicable for most of Texas and represent the most intense storms. The Type III curves are similar in shape to the Type II curves. The Type II and III curves shown in figure 4 indicate most rain would fall during the period that is between 45 and 55 percent of the storm duration.

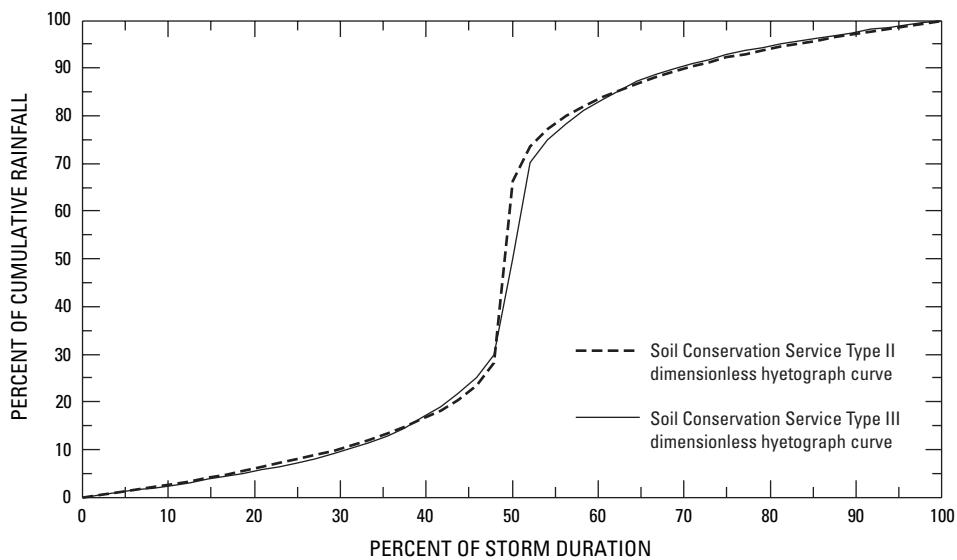

#### Research by Pani and Haragan

The approach used by Pani and Haragan (1981) followed the approach used by Huff (1967), and results of the two studies

were similar. Details of the approach used by Huff (1967) and clarification of the terminology used in this section are provided in the “Research by Huff” section of this report.

Pani and Haragan (1981) classified storms into four quartiles depending upon which quarter of dimensionless storm time had the greatest change in cumulative rainfall. Data were analyzed for 117 storms that occurred between May 15 and July 31 for a 3-year period (1978–80). Data for the analysis were collected from a rain-gage network that was operated as part of the High Plains Cooperative Program (HIPLEX) (Texas Department of Water Resources, 1980). The rain-gage network was located near Big Spring in the southern High Plains of Texas and encompassed about 2,600 square miles (Pani and Haragan, 1981). Data used in the analysis consisted of 15-minute rainfall values. The mid-May through July period was selected to confine the HIPLEX study to the period when convective-generated precipitation was most likely to occur. A storm was defined as a “rain period of at least 0.75-hour duration separated from preceding and succeeding rain periods by at least 1 hour” (Pani and Haragan, 1981).

In Pani and Haragan (1981), the relative frequencies of the storms were 13, 41, 32, and 14 percent for the first, second, third, and fourth quartiles, respectively. These frequencies indicate 73 percent of the storms were classified as second and third quartile. In Huff (1967, 1990), 66 percent of the storms were classified as first and second quartile. The chi-square goodness-of-fit test given in Davis (1986) and used in Pani and Haragan (1981) indicated significant differences in the relative frequencies for the two studies. Pani and Haragan (1981) stated that these differences could be attributed to advecting storm systems

**Figure 4.** Soil Conservation Service Type II and Type III hyetograph curves. (Modified from Asquith and Thompson, 2003.)

across a network that was six times larger in areal extent than the Illinois network used by Huff (1967, 1990). Pani and Haragan (1981, p. 78) concluded that “if a storm’s areal extent was larger than the network, which is often the case in Illinois, the resultant temporal distribution would show more rain falling during the early portion of the network lifetime and produce a classification in the first quartile.” Thus, as a network area increases, more storms will be characterized as central peaking. Huff (1967) reached a similar conclusion.

The conclusions reached by Huff (1967) and Pani and Haragan (1981) are relevant to the research presented in this report. The accumulated weighted-precipitation amounts given in the database for each storm were derived from one to as many as six rain gages and were assumed to be representative of rainfall amounts across drainage areas that ranged from 0.26 to 166 square miles. Most drainage areas for this study were less than 20 square miles, and only two or three rain gages were in operation. Thus, the “network scale” in the database is very small in relation to the network scales used by Huff (1967, 1990) and Pani and Haragan (1981).

The median (50th-percentile) dimensionless hyetograph curves shown in figure 5 for the southern High Plains of Texas were graphically extracted from figures given in Pani and Haragan (1981). Curves are shown for second- and third-quartile storms. The chi-square test indicated no significant differences between the curves derived in Huff’s (1967) study and the curves derived in Pani and Haragan’s (1981) study. Thus, although the relative frequencies of the storms in Illinois were statistically different from the storms in Texas, the hyetograph curves were not statistically different. Hyetograph curves were

not provided for first- and fourth-quartile storms because of small sample sizes for those quartiles (Pani and Haragan, 1981).

Because the rate of change in the cumulative-rainfall amount for third-quartile storms was greatest near 55 percent of the storm duration (fig. 5), Pani and Haragan (1981) concluded that second- and third-quartile storms were similar enough to be combined for design applications. The median (50th-percentile) composite dimensionless hyetograph curve for the combined storms is shown in figure 6 along with the 10th- and 90th-percentile composite curves for the southern High Plains of Texas. Pani and Haragan (1981) did not consider the effects of storm duration on the hyetograph curves.

## Approach

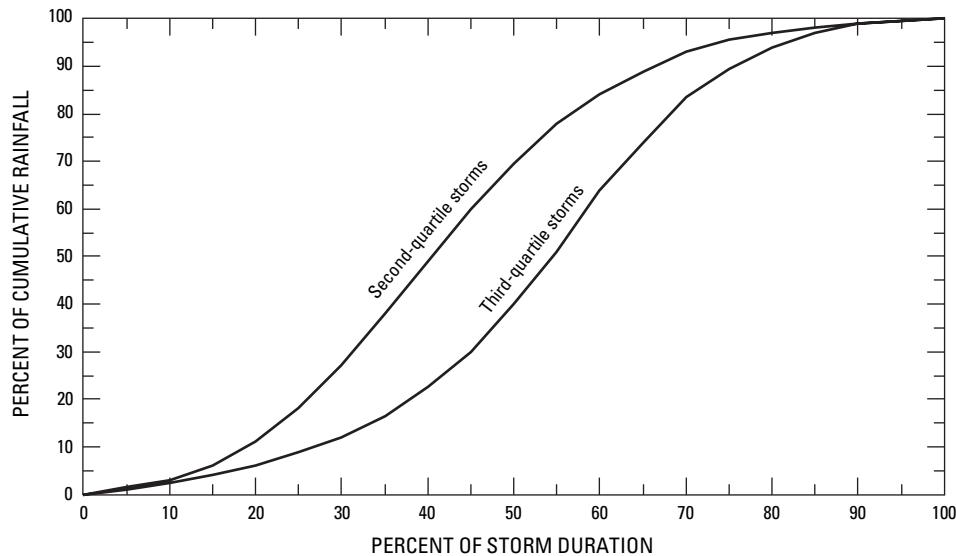

For this study, the general approach given by Huff (1967, 1990) was used to determine storm-quartile classifications from cumulative-rainfall values given in the database. The storm-quartile classification depended upon when the heaviest rate of rainfall occurred during the storm duration. For example, the total storm duration was divided into quarters and then the change in rainfall during each quarter was determined. The quarter that had the greatest change was used as the quartile classification. The cumulative-rainfall values were divided into data groups on the basis of storm-quartile classification (first, second, third, fourth, and first through fourth combined), storm duration (0 to 6, 6 to 12, 12 to 24, 24 to 72, and 0 to 72 hours), and rainfall amount (1 inch or more). Of the 1,659 runoff-producing storms for which data are available, 1,507 met the criteria for the storm duration (the number of hours passed) and

## 6 Empirical, Dimensionless, Cumulative-Rainfall Hyetographs for Selected Small Watersheds in Texas

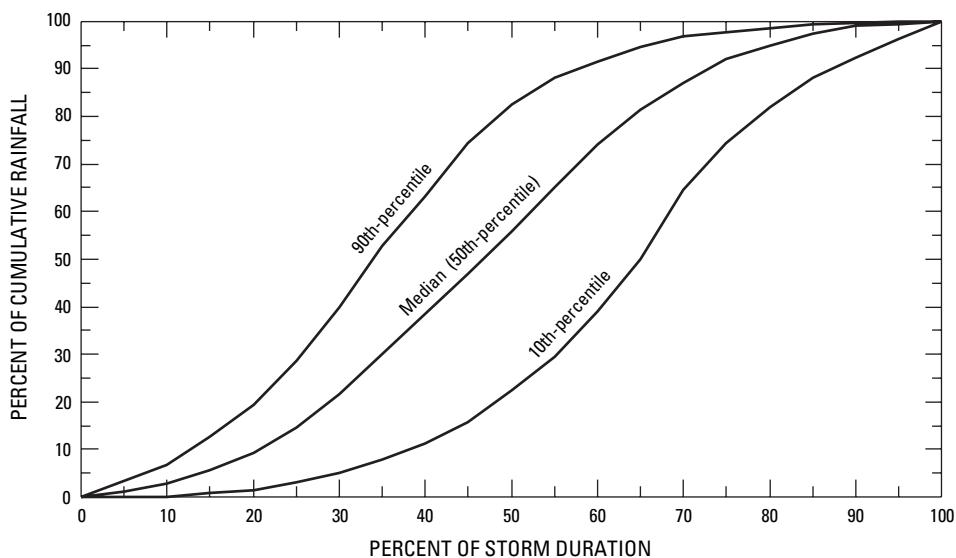

the rainfall amount (the accumulated weighted-precipitation amount).

For some storms, the starting and ending times given in the database were not coincident with the starting and ending times of a substantial amount of rainfall that produced runoff. Some of the storms had long leading tails (the number of hours that passed before a measurable amount of rainfall

occurred) that were an artifact of the method by which the original data were recorded and that give the numerical impression that a storm duration is longer than the actual storm duration. Thus, if more than 1 hour had passed before a measurable amount of rainfall occurred, the leading tails were removed by changing the HOURS\_PASSED value in the hyetograph data file [see Asquith and others (2004) for specific details about the database]. For example, in the data file shown

**Figure 5.** Median (50th-percentile) dimensionless hyetograph curves for the southern High Plains of Texas. (Modified from Pani and Haragan, 1981.)

**Figure 6.** Median (50th-percentile), 10th-, and 90th-percentile composite dimensionless hyetograph curves for the southern High Plains of Texas. (Modified from Pani and Haragan, 1981.)

in figure 7, 21.5833 hours passed (HOURS\_PASSED) before the first 0.35 inch of rainfall (ACCUM\_WTD\_PRECIP) was recorded. Thus, to remove the long leading tail, the zero HOURS\_PASSED value shown in figure 7A was changed to the 21.5833 HOURS\_PASSED value shown in figure 7B. Removal of the leading tail, in effect, shortened the storm duration, and, in some cases, affected the storm-quartile classification. Thus, the storm-quartile classifications were re-evaluated and a second group of data was generated. The original group of data is known as the untrimmed data group, and the second group of data is known as the trimmed data group.

After the storm-quartile classifications were re-evaluated, a double-tail 1-percent trimming was conducted to further reduce the length of both the leading and ending tails. The percentages of cumulative rainfall and storm duration then were recomputed. To accomplish the double-tail trimming, storms were considered to start after 1 percent or more of the cumulative-rainfall amount occurred and to stop after 99 percent of the cumulative-rainfall amount occurred.

After the double-tail 1-percent trimming was conducted, data for each cumulative-rainfall hyetograph were converted into data for a dimensionless hyetograph analysis. In dimensionless hyetographs, units of time and rainfall are expressed as percentages of the respective totals. Therefore, the time increments were converted to a percentage of storm duration, and the rainfall amounts were converted to a percentage of the cumulative-rainfall amount. The percentages of cumulative rainfall then were separated into bins and used to generate probability percentiles, averages, variances, standard deviations, and counts (number of samples) for each bin. The percentages were separated into bins by dividing the percentage of storm duration (the hours passed) into 2.5-percent intervals and by determining the percentage of cumulative rainfall that fell within each interval. The centers of the 2.5-percent intervals began at 2.5 percent and ended at 97.5 percent. Zero and 100 were included in the nearest respective increment. No interpolation, linear or otherwise, was used to determine in which bin the percentage of cumulative rainfall fell. For the example dimensionless hyetograph data given in table 1, the percentage of cumulative rainfall (the accumulated weighted-precipitation amount) for the 2.5-percent bin (0 to 3.75 hours passed) is 6.522, the percentage for the 5-percent bin (3.75 to 6.25 hours passed) is 8.696, the percentage for the 7.5-percent bin (6.25 to 8.75 hours passed) is 9.420, and the percentage for the 10-percent bin (8.75 to 11.25 hours passed) is 11.59.

The number of percentages within each bin varied, and some bins had no values. Also, because the statistics for each bin varied, the dimensionless hyetograph curves that were developed from the data might not have been monotonically increasing. Therefore, to obtain the monotonically increasing curves desired for design applications, the data were adjusted using manual adjustments and a Friedman (1984) Supersmoothing program in the S-PLUS statistics package (release 3).

Statistics for the untrimmed and trimmed data groups are given in supplements 2 through 5. The probability percentiles given in supplements 4 and 5 are the same as those given in supplements 2 and 3, but the percentiles given in supplements 4 and 5 were smoothed to ensure monotonic increases.

Averages and ranges for the cumulative-rainfall amounts for the untrimmed and trimmed data groups are given in table 2. The distribution of storm occurrences for both groups is given in table 3. Removing the leading tails increased the first-quartile occurrences for all storm durations. The second- and third-quartile occurrences increased for storm durations of 0 to 6 and 6 to 12 hours, and the fourth-quartile occurrences increased slightly for a storm duration of 0 to 6 hours.

For a 12-hour or less trimmed storm duration, approximately 49 percent of the storms are first quartile. For trimmed storm durations of 12 to 24 and 24 to 72 hours, 47 and 38 percent, respectively, of the storms are first quartile. These results are slightly different from those given by Pani and Haragan (1981) who classified most storms in Texas as second and third quartile. For a storm duration of 0 to 72 hours, the first-, second-, third-, and fourth-quartile storms in the trimmed data group accounted for 46, 21, 20, and 13 percent of all storms, respectively.

The distributions of storm occurrences by storm duration and by storm-quartile classification are shown in figures 8 and 9, respectively. The distributions were similar and typical of storm activity in the central part of Texas for all durations and for all quartile classifications. During the spring, convective storms are enhanced by frontal systems. During the fall, convective storms are enhanced by frontal and tropical systems. Dividing the hyetograph data groups into distinct spring and fall periods was not included in the scope of this study but might be helpful in further defining storm hyetographs.

## **Empirical, Dimensionless, Cumulative-Rainfall Hyetographs**

Probability percentiles allow the selection of a time distribution that is most appropriate for a particular application. In some cases, a median (50th-percentile) distribution of rainfall with time might be most useful, and, in other cases, 10th- to 90th-percentile distributions of rainfall with time might be most useful. The median dimensionless hyetograph curves for first- through fourth-quartile storms and for the first- through fourth-quartile storms combined are shown in figure 10 for a storm duration of 0 to 72 hours. The 10th- to 90th-percentile curves are shown in figure 11. The curves shown in the figures are for the trimmed and smoothed data group. Curves for the untrimmed data group were similar to curves for the trimmed data group. Smoothed median (50th-percentile) distributions of rainfall with time are given in table 4.

**Figure 7.** Untrimmed (A) and trimmed (B) hyetograph data files. (Removal of the long leading tail was accomplished by changing the zero HOURS\_PASSED value shown in bold to the 21.5833 HOURS\_PASSED value shown in bold.)

Selected percentiles for the first- and second-quartile storms are given in table 5. The 90th-percentile curve shown in figure 11 for first-quartile storms is typical of storms in which the rainfall occurs during a short period of time—that is, for 1 of 10 first-quartile storms, about 91 percent of the rainfall occurs during the first quarter of the storm and about 98 percent of the rainfall occurs during the first half of the storm. The 50th-percentile curve indicates about 69 percent of the rainfall occurs during the first quarter of the storm and about 85 percent of the

rainfall occurs during the first half of the storm. The 10th-percentile curve indicates about 39 percent of the rainfall occurs during the first quarter of the storm and about 58 percent of the rainfall occurs during the first half of the storm. The 90th-percentile curve for second-quartile storms indicates about 69 percent of the rainfall occurs during the first quarter of the storm and about 89 percent of the rainfall occurs during the first half of the storm. The 50th-percentile curve indicates about 28 percent of the rainfall occurs during the first quarter of the

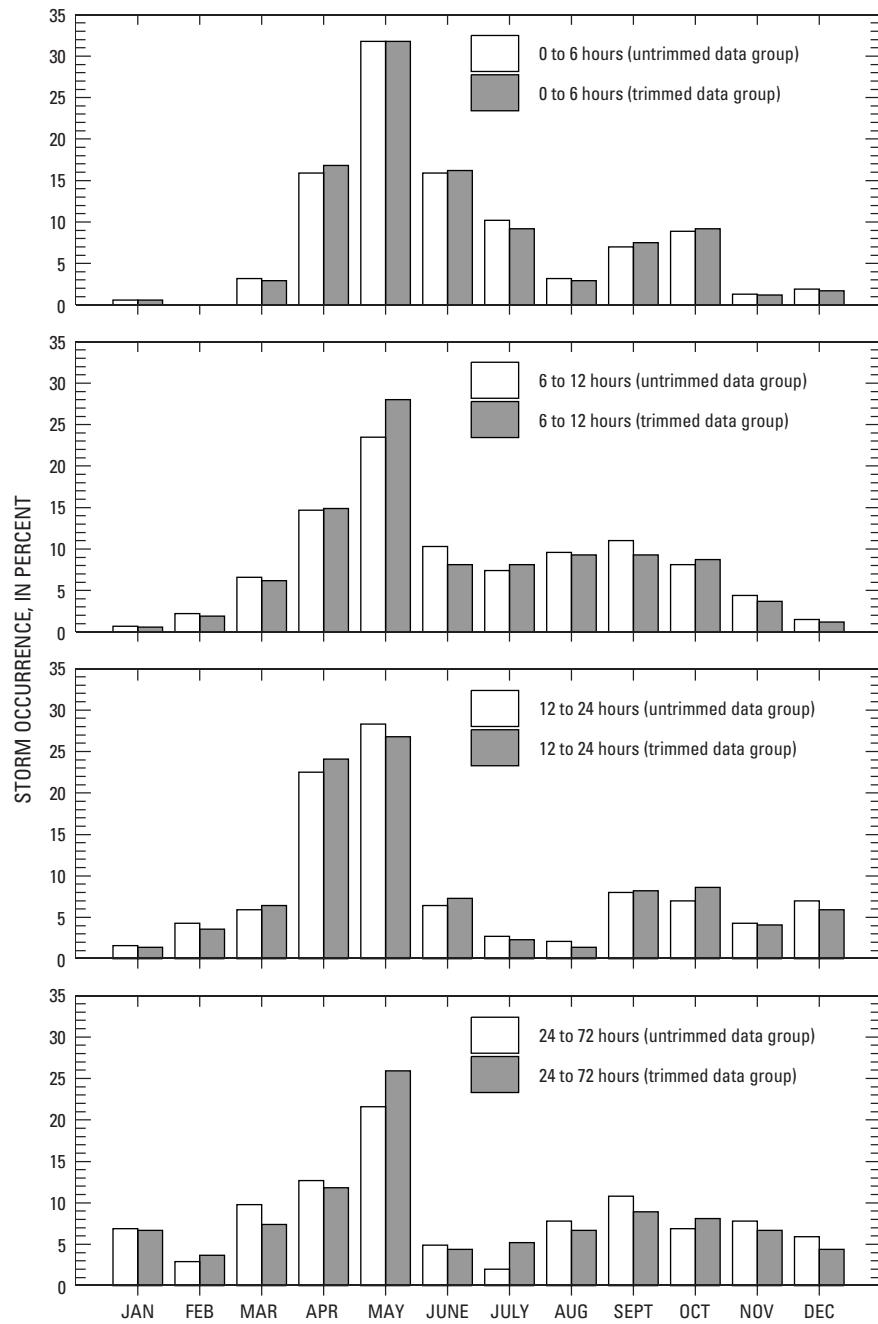

Figure 8. Distribution of storm occurrences by storm duration.

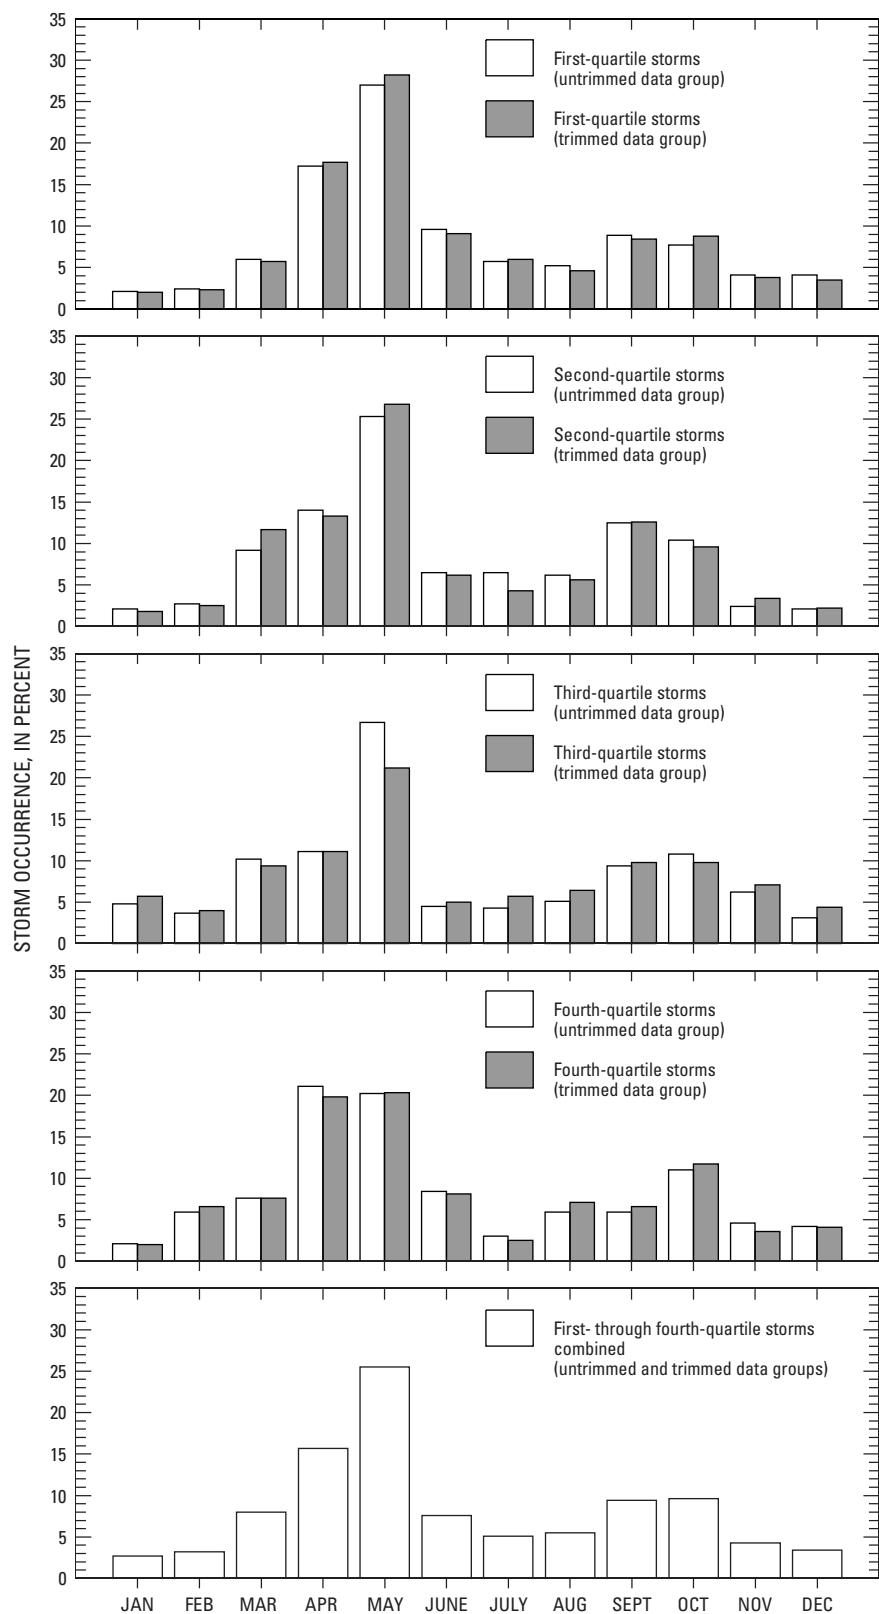

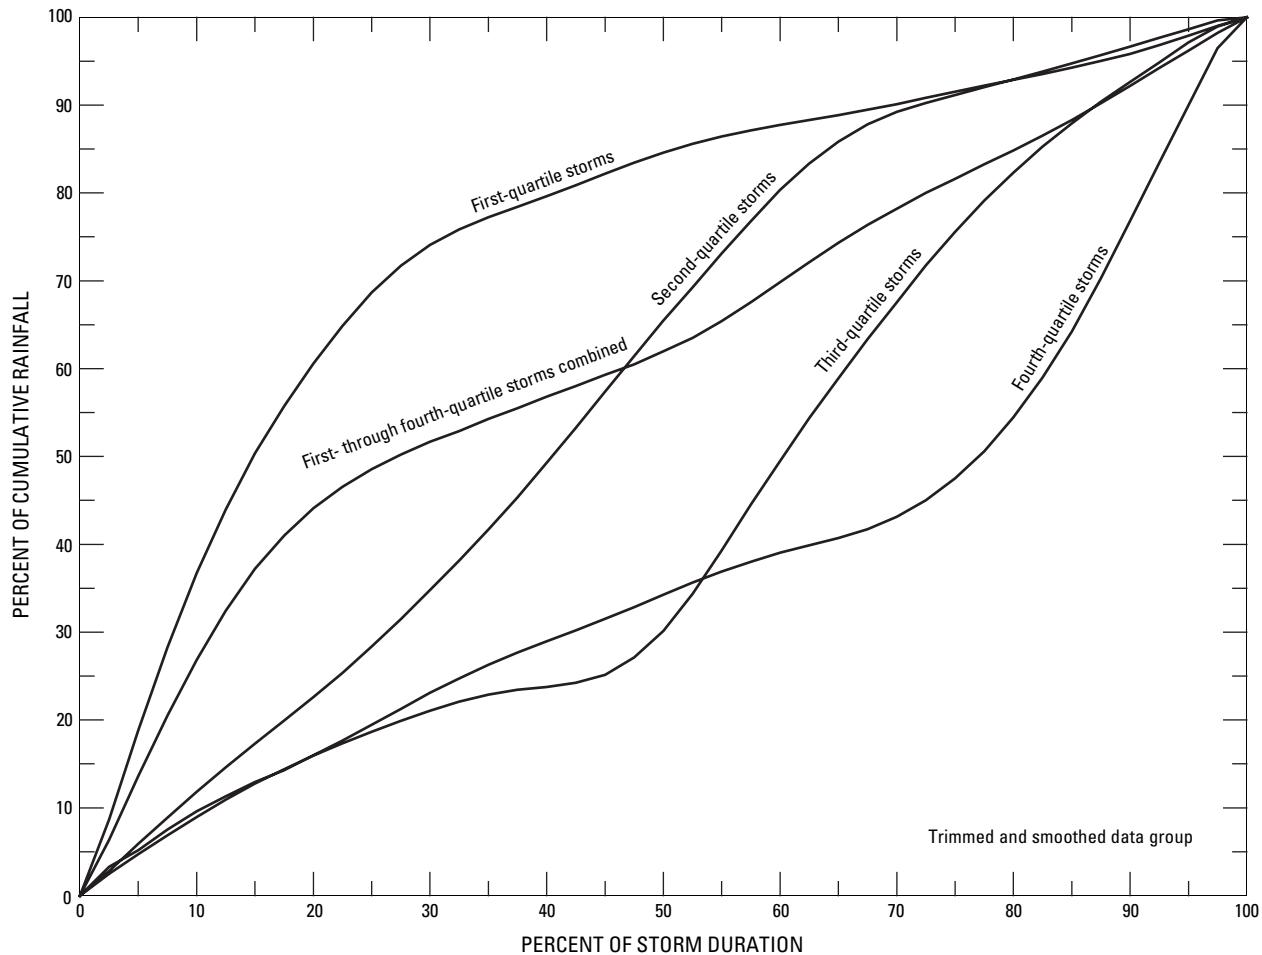

Figure 9. Distribution of storm occurrences by storm-quartile classification.

**Figure 10.** Median (50th-percentile) dimensionless hyetograph curves for a storm duration of 0 to 72 hours and a rainfall total of 1 inch or more.

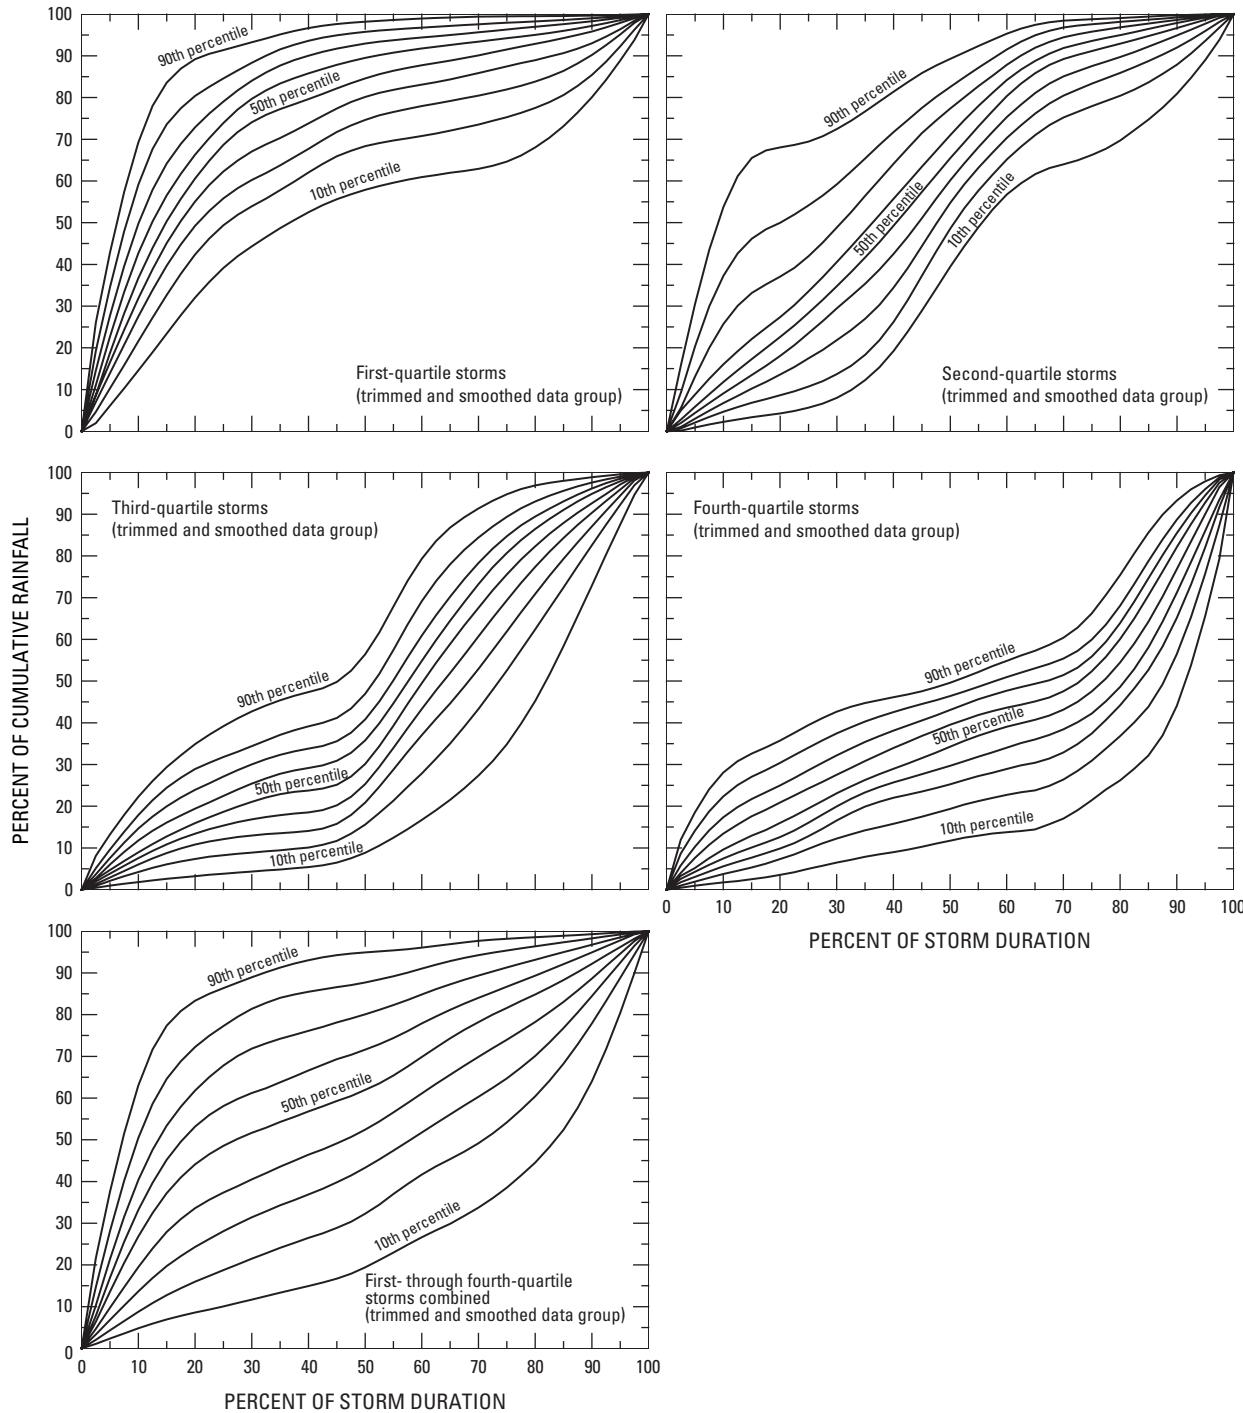

storm and about 65 percent of the rainfall occurs during the first half of the storm. The 10th-percentile curve indicates about 6 percent of the rainfall occurs during the first quarter of the storm and about 39 percent of the rainfall occurs during the first half of the storm.

Selected percentiles for the third- and fourth-quartile storms are given in table 6. The 90th-percentile curve shown in figure 11 for third-quartile storms indicates about 39 percent of the rainfall occurs during the first quarter of the storm and about 56 percent of the rainfall occurs during the first half of the storm. The 50th-percentile curve indicates about 19 percent of the rainfall occurs during the first quarter of the storm and about 30 percent of the rainfall occurs during the first half of the storm. The 10th-percentile curve indicates about 4 percent of the rainfall occurs during the first quarter of the storm and about 9 percent of the rainfall occurs during the first half of the storm. The 90th-percentile curve for fourth-quartile storms indicates about 39 percent of the rainfall occurs during the first quarter of the storm and about 50 percent of the rainfall occurs during the first half of the storm. The 50th-percentile curve indicates about

19 percent of the rainfall occurs during the first quarter of the storm and about 34 percent of the rainfall occurs during the first half of the storm. The 10th-percentile curve indicates about 5 percent of the rainfall occurs during the first quarter of the storm and about 12 percent of the rainfall occurs during the first half of the storm.

The hyetograph curves for the various percentiles indicate characteristics of certain storm types. For example, the 90th-percentile curve for first-quartile storms (fig. 11) indicates about 90 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 10th-percentile curve for first-quartile storms indicates about 30 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 90th-percentile curve for fourth-quartile storms indicates about 33 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 10th-percentile curve for fourth-quartile storms indicates less than 5 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 90th-percentile curves for the second- and third-quartile storms indicate about 67 and

## 12 Empirical, Dimensionless, Cumulative-Rainfall Hyetographs for Selected Small Watersheds in Texas

**Figure 11.** 10th- to 90th-percentile dimensionless hyetograph curves for a storm duration of 0 to 72 hours and a rainfall total of 1 inch or more.

33 percent, respectively, of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 10th-percentile curves for the second- and third-quartile storms indicate about 5 and less than 1 percent, respectively, of the cumulative rainfall occurs during the first 20 percent of the storm duration.

The hyetograph curves and tables presented in this report were empirically derived and do not present exact mathematical relations. However, the curves and tables can be used to estimate distributions of rainfall with time for small drainage areas of less than about 160 square miles in urban and small rural watersheds in Texas.

**Table 1.** Example dimensionless hyetograph data.

## Summary

A database of incremental cumulative-rainfall values for 1,659 runoff-producing storms that occurred during the period from 1959 to 1986 at or proximate to 91 U.S. Geological Survey streamflow-gaging stations located in small urban and rural watersheds in north and south central Texas was used to develop empirical, dimensionless, cumulative-rainfall hyetographs. Storm durations ranged from a few hours to several days, and cumulative-rainfall amounts ranged from less than 1 inch to more than 10 inches. Drainage areas for the 91 streamflow-gaging stations ranged from 0.26 to 166 square miles; however, drainage areas for 72 of the stations were less than 20 square miles.

Storm-quartile classifications were determined from the cumulative-rainfall values, which were divided into data groups on the basis of storm-quartile classification (first, second, third, fourth, and first through fourth combined), storm duration (0 to 6, 6 to 12, 12 to 24, 24 to 72, and 0 to 72 hours), and rainfall amount (1 inch or more). The storm-quartile classification depended upon when the heaviest rate of rainfall occurred during the storm duration. Removal of long leading tails, in effect, shortened the storm duration, and, in some cases, affected the storm-quartile classification. Therefore, two storm groups, untrimmed and trimmed, were used for analysis. The trimmed storms generally are preferred for interpretation. For a 12-hour or less trimmed storm duration, approximately 49 percent of the storms are first quartile. For trimmed storm durations of 12 to 24 and 24 to 72 hours, 47 and 38 percent, respectively, of the storms are first quartile. For a trimmed storm duration of 0 to 72 hours, the first-, second-, third-, and fourth-quartile storms accounted for 46, 21, 20, and 13 percent of all storms, respectively.

The 90th-percentile curve for first-quartile storms indicated about 90 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 10th-percentile curve for first-quartile storms indicated about 30 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 90th-percentile curve for fourth-quartile storms indicated about 33 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration. The 10th-percentile curve for fourth-quartile storms indicated less than 5 percent of the cumulative rainfall occurs during the first 20 percent of the storm duration.

Statistics for the empirical, dimensionless, cumulative-rainfall hyetographs are presented in the report along with hyetograph curves and tables. The hyetograph curves and tables presented do not present exact mathematical relations but can be used to estimate distributions of rainfall with time for small drainage areas of less than about 160 square miles in urban and small rural watersheds in Texas.
