# A Regional Framework of Early Growth Response for Loblolly Pine Relative to Herbaceous, Woody, and Complete Competition Control: The COMProject

James H. Miller, Bruce R. Zutter, Shepard M. Zedaker, M. Boyd Edwards, and Ray A. Newbold

#### SUMMARY

A common study design has been installed at 13 locations throughout the Southeastern United States to track the growth of loblolly pine (*Pinus taeda* L.) plantations established with four different competition control treatments: no control (only chopping-burning), woody control for 5 years, herbaceous control for 4 years, and total control after site preparation. This regionwide investigation is known as the Competition Omission Monitoring Project, a coordinated study with the Auburn University Silvicultural Herbicide Cooperative (Study HB-4F). Data summaries for each location are presented for loblolly pine growth and competition intensities for the first 8 years. Approximately 10,000 loblolly pine seedlings have been measured annually. Responses from this network of studies should be useful in assessing and reporting relative growth of loblolly pines for other studies and operational plantings. These data sets should also be useful for future forest growth modeling efforts.

## A Regional Framework of Early Growth Response for Loblolly Pine Relative to Herbaceous, Woody, and Complete Competition Control: The COMProject

James H. Miller, Bruce R. Zutter, Shepard M. Zedaker, M.Boyd Edwards, and Ray A. Newbold

#### INTRODUCTION

Numerous studies have been established during the past 20 years to examine the influence of herbaceous and woody vegetation on the growth of loblolly pine (Pinus taeda L.) across the Southeastern United States. However, few studies can be compared due to differences in site growth potential, treatment timing and duration, experimental design, and pine density, to list a few. Researchers in forest vegetation management need a logical context wherein crop-tree growth at various sites can be compared to levels of competition or to a maximum potential growth response. To assist in developing this comparison network, a group of investigators established a regionwide study to determine the standard growth response of loblolly pine to four competition situations (Miller and others 1987, 1991). The four treatments, or competition situations, are as follows:

- 1. No **control,** with a mixture of woody and herbaceous competitors;
- 2. **Woody control,** leaving herbaceous competitors;
- 3. **Herbaceous control,** leaving woody competitors; and
- 4. **Total control,** devoid of all competition. In this simple framework, arborescent hardwoods and nonarborescent shrubs are combined as woody competition; forbs, grasses, vines, and semiwoody (e.g., black-

berry) vegetation comprise the herbaceous component.

The four treatments used in this study are "extremes" because each focuses specifically on complete component or complete competition control compared to no control. These four treatments encompass the full range of competition conditions that are common to young loblolly pine plantations. Partial competition control treatments, which are used in operating plan-

tations, lie among these extremes. The growth response to partial control can be gauged relative to the results of these extreme treatments reported here. This comparative gauging should be most useful in research reporting of partial control treatments.

One objective of the Competition Omission Monitoring Project (COMProject or COMP) investigation is to establish a network of growth responses for loblolly pines when these four treatments are used on major soil types across the region. The other objectives of COMP are to compare the relative importance of herbaceous vs. woody competition as they affect the growth of loblolly pines on the wide range of sites across the region, to identify the major herbaceous and woody competitors and document early succession, and to study the interaction of competition and pine growth on insect and disease infection. These last three objectives have been or will be addressed in other reports from this research group (Miller and others 1987, 1991, 1995).

Mean pine growth response and competition response by treatment that has occurred at 13 plantation locations are presented in this report. For those readers interested in treatment comparisons and the errors associated with treatments, please refer to the other papers in this series or contact the authors (Miller and others 1987, 1991; Zutter and others, in press).

#### **METHODS**

#### **Study Sites**

A common study design was used at 13 plantation sites across four physiographic provinces-the Lower, Middle, and Hilly Coastal Plains and Piedmont-in

James H. Miller is a research ecologist at the Forestry Sciences Laboratory, U.S. Department of Agriculture, Forest Service, Southern Forest Experiment Station, Auburn University, Auburn, AL 36849; Bruce R. Zutter is a research associate at the School of Forestry, Auburn University, Auburn, AL 36849; Shepard M. Zedaker is a professor at the Department of Forestry, Virginia Tech University, Blacksburg, VA 24061; M. Boyd Edwards is a research ecologist at the Georgia Forestry Center, U.S. Department of Agriculture, Forest Service, Southeastern Forest Experiment Station, Dry Branch, GA 31020; Ray A. Newbold is an associate professor at the School of Forestry, Louisiana Tech University, Ruston, LA 71272.

Alabama, Arkansas, Georgia, Louisiana, Mississippi, Tennessee, and Virginia (table 1; fig. 1). Prior to plot establishment, pine plantations or mixed pine-hardwood stands were harvested in late 1982 or in 1983. Site preparation was by roller-drum chopping and prescribed burning at 10 study locations. A shear, pile, and burn method was used at **Counce**, Tennessee, which resulted in some topsoil removal and displacement into the windrows. A complete harvest of fuelwood and pines was used at Atmore, Alabama; the Lower Coastal Plain site near Pembroke, Georgia, was simply rebedded after a wildfire destroyed a young plantation that had been previously windrowed. A naturally regenerated plantation site has also been established using these treatments and is reported elsewhere (Cain 1991).

To characterize the soils at each location, USDA Soil Conservation Service soil surveyors or forest industry soil surveyors examined each site (table 1). To further characterize the soils, samples were collected at each location in April 1984. From each plot, 20 soil-

tube samples were extracted from three depths: 0 to 6, 6 to 12, and 12 to 24 inches. For each plot, samples were combined by depth, thoroughly mixed, and stored in a cold room until analysis. Samples were then air-dried and crushed to pass through an 80-mesh sieve. Duplicate samples were analyzed for available phosphorus (P), calcium (Ca), magnesium (Mg), and potassium (K) after extraction with a Mehlich I solution (Mehlich 1953). Organic matter determinations were according to Jackson (1958), and pH determinations used a 1:1 soil-to-water mixture and a pH meter. Soil texture was determined by the hydrometer method. A summary of the results of these analyses is presented in table 2.

#### **Plot Layout**

Four blocks of 4 plots each were established at 11 of the 13 locations using a factorial, randomized, complete-block design. At Pembroke, Georgia, a fifth block

'Measurement of these soil properties not made at this location.

was included, and at Bainbridge, Georgia, a completely randomized design was used. Treatment plots were generally 0.25 acre in size, and interior measurement plots were 0.09 acre. Precisely measured planting spots on a 9- by 9-ft spacing were used at all but the machine-planted locations at Pembroke, Georgia, and Arcadia, Louisiana (table 1). This spacing resulted in 538 trees per acre (565 and 622 trees per acre at the machine-planted locations), with 49 measurement pines in the interior plots and 2 border rows surrounding the measurement plots.

At most sites, two regraded 1-O loblolly pine seedlings were planted at each spot, 10 to 12 inches apart. Either genetically improved or Livingston Parish, Louisiana, seedlings were used. After the first growing season, double-planted seedlings were thinned to one per spot using randomly generated codes to maintain the original population characteristics. Double planting was used to minimize variations in initial survival and the resulting long-term variation that occurs with unequal stocking. Only single seedlings were planted at Pembroke, Georgia, Arcadia, Louisiana, and Liberty, Mississippi, where adequate survival resulted in stocking levels comparable to the other locations. Measurement trees were permanently tagged. Volunteer pines were repeatedly removed from all locations except Appomattox, Virginia, where Virginia pine (Pinus virginiana Mill.) was left on woody competition plots because it is considered to be a common woody competitor in that area.

#### **Establishment of Competition Situations**

Four treatments, or competition situations, were established and maintained as follows:

No **Control Resulting in Mixed Herbaceous-Woody Competition.**-After initial site preparation, no further treatments were applied except for tree injection of scattered, large, residual hardwoods using triclopyr (Garlon®).

Woody Control Only Resulting in Herbaceous Competition.-Both foliar and basal sprays, as well as basal wipes, were used to control hardwoods and shrubs during the first 5 years. A single preplant and multiple postplant applications per year were made, usually with directed sprays of glyphosate (Roundup@), triclopyr, and picloram (Tordon®) or basal wipes of triclopyr and diesel fuel. After planting, only herbicides with no soil activity were used to minimize any potential damage to herbaceous plants and measurement pines.

Herbaceous Control Only Resulting in Woody Competition.-Preemergent applications of sulfometuron (Oust@ at 3 to 6 oz/acre) were applied annually for the first 4 years to control forbs and grasses. The most effective rate, having the least pine toxicity, was

determined through screening trials on nearby sites at most locations during the year prior to establishment. After the first year, either glyphosate (Roundup at 18 oz/acre) or oxyfluorfen (Goal@ at 0.6 gal/acre) were commonly added to the tank mix with sulfometuron. One to five times during a growing season, shielded, directed sprays of glyphosate (a Roundup 2-percent solution) were applied to perennial grasses, resistant forbs, and vines. At Bainbridge, Georgia, sethoxydim (Poast® or Vantage@) was broadcast sprayed for grass control in the second year.

**Total Control Resulting in Elimination of All Competition.-A** combination of the treatments discussed above were used to control both woody and herbaceous competition.

Complete eradication of woody or herbaceous components was rarely achieved, especially in the first and second years. But significant reductions were made, and desired competition situations were obtained, with persistent applications at most locations. Herbaceous control treatments were applied for 4 years, whereas control levels persisted for several more years, even to year 8 on some sites. Woody control treatments were applied for 5 years, although the completeness and duration of control varied by location. Minimal crop-pine damage was observed with these treatments.

### **Measurements and Analyses**

Pine size was determined immediately after planting by randomly selecting 100 seedlings (50 at Appomattox, Virginia) and measuring groundline diameter and height for each. Seedling pines were then measured annually in the dormant season for total height (nearest 0.1 ft) for years 1 through 8, and height-to-live-crown was measured in years 5 through 8. The height-to-live-crown was measured along the bole to the first branch with live foliage. Groundline diameters were measured in years 1 through 5, diameters at 6-inch height were measured in years 2 through 5, and diameters at breast height (d.b.h.'s) were measured in years 3 through 8-all to the nearest 0.1 inch. Stocking records of surviving trees were maintained for the first 8 years. Approximately 10,000 pine seedlings were measured annually.

Basal area was calculated by summing the stem area at breast height for all surviving trees. An individual tree volume index for years 3 through 8 was estimated using (d.b.h.²/144 x height) 13-a modified conical projection-and summed for all surviving trees. Basal area and tree volume indices were expanded to an acre basis by multiplying by the appropriate expansion factor for the measurement plot.

Within each interior measurement plot, three 9- by 18-ft sample plots were systematically established,

with the corners at pine planting spots-a O.Ol-acre sample per 0.09-acre measurement plot yielding a 12-percent sample. Annually in September of years 1 through 5 and in year 8, all woody rootstocks taller than 0.5 ft were recorded by species (genus for some shrubs) and height class. Rootstocks were those judged to originate from the same central root system with one or more stems. Height classes were delineated by 1-ft intervals up to 12 ft and then by 5-ft intervals. In years 5 and 8, all arborescent hardwood rootstocks exceeding 5 ft in height within the measurement plots were counted, and d.b.h.'s were measured, yielding a basal area estimate.

For cover estimates, the three 9- by 18-ft sample plots were halved to yield six 9- by 9-ft subplots per measurement plot. Annually in September for years 1 through 8, cover was visually estimated within each subplot for the herbaceous life-forms and for any "no cover" that lacked any vegetation above the area. The herbaceous life-forms were as follows: grasses and grasslike plants, forbs, vines, and semiwoody plants (e.g., blackberries and dewberries, Rubus spp., and St. John's wort, Hypericum spp.). Starting in year 2, estimates were added for "total woody cover" and for "planted pine" cover. All cover estimates were grouped into one of the following percentage classes (range): 0, 2 (1 to 5), 10 (6 to 15), 20 (16 to 25), 30 (26 to 35), 40 (36 to 45), 50 (46 to 55), 60 (56 to 65), 70 (66 to 75), 80 (76 to 85), 90 (86 to 95), 97 (96 to 99), and 100. This grouping permitted the more accurate cover estimates that can be made at the extremes.

#### **RESULTS AND DISCUSSION**

Initial seedling sizes are presented in table 3. The COMP growth response values presented in tables 4 through 16 represent biological standards for loblolly pine on these specific soil-sites, relative to their competition levels that are presented in tables 17 through 42. Greater levels of herbaceous control were evident in the spring and early summer immediately after broadcast herbicide applications. To assist future modeling efforts, table 43 presents mean total height of

the tallest 100, 200, 300, and 400 pines per acre by treatment for each location at year 8.

Sizes and growth increments of pines grown completely in the absence of competition (total control) approach as absolute a value as there is in forest vegetation management relating pine growth to site productivity Less absolute because of varying levels of herbaceous competition, but a useful benchmark, are growth-response values on plots with woody control. The pine growth with the other two treatments-no control and herbaceous control-provide an estimate of pine-growth loss relative to these "benchmarks" from given densities of hardwoods on the sites.

Studies of pine growth with herbaceous control on similar soil sites can be compared to growth results from total control and woody control (maximum herbaceous cover with no woody plants) for any period between years 1 and 8. Either actual or relative growth increases can be used for making comparisons with other plantings. Volume index is the best integrating value for comparisons, but heights and diameters can also be used. It is recognized that diameters respond more, proportionally, to competition control than heights do, whereas heights can even be increased by severe woody competition (Miller and others 1991). The large numbers of plots and trees in this study result in small sampling error for the means. In effect, researchers using data from a smaller trial for comparisons could often assume that the values reported are "true" values and could test for differences using the trial data errors alone.

For comparison of woody control treatments or herbicide treatments that control both woody and herbaceous plants, comparisons with the total control would be best for judging the pine-growth response relative to a potential response with no competitors. For comparing plantings and plots where spacing is other than 538 trees per acre, the average individual tree-growth response may be used for the first few years. The average tree response can be obtained by dividing the volume index per acre by the stocking. The proportional gain on COMP sites can also be used to judge pine-growth response for other forest cultural treatments (e.g., disking, subsoiling, fertilization, etc.) from similar sites.

## PESTICIDE PRECAUTIONARY STATEMENT

Pesticides used improperly can be injurious to humans, animals, and plants. Follow the directions and heed all precautions on the labels.

Store pesticides in original containers under lock and key-out of the reach of children and animals-and away from food and feed.

Apply pesticides so that they do not endanger humans, livestock, crops, beneficial insects, fish, and wildlife. Do not apply pesticides when there is danger of drift, when honey bees or other pollinating insects are visiting plants, or in ways that may contaminate water or leave illegal residues.

Avoid prolonged inhalation of pesticide sprays or dusts; wear protective clothing and equipment if specified on container.

If your hands become contaminated with a pesticide, do not eat or drink until you have washed. In case a pesticide is swallowed or gets in your eyes, follow the first-aid treatment given on the label, and get prompt medical attention. If a pesticide is spilled on your skin or clothing, remove clothing immediately and wash skin thoroughly.

Do not clean spray equipment or dump excess spray material near ponds, streams, or wells. Because it is difficult to remove all traces of herbicides from equipment, do not use the same equipment for insecticides or fungicides that you use for herbicides.

Dispose of empty pesticide containers promptly according to Federal, State, and local laws and regulations.

NOTE: Some States have restrictions on the use of certain pesticides. Check your State and local regulations. Also, because registrations of pesticides are under constant review by the Federal Environmental Protection Agency, consult your county agricultural agent or State extension specialist to be sure the intended use is still registered.

Miller, James H.; Zutter, Bruce D.; Zedaker, Shepard M.; Edwards, M. Boyd; Newbold, Ray A. 1995. A regional framework of early growth response for loblolly pine relative to herbaceous, woody, and complete competition control-The **COMProject**. Gen. Tech. Rep. SO-117. New Orleans, **LA**: U.S. Department of Agriculture, Forest Service, Southern Forst Experiment Station. 48 p.

A common study design has been installed at 13 locations throughout the South to track the growth of loblolly pine (*Pinus taeda* L.) plantations established with 4 different competition control treatments: no control (only chopping-burning), woody control for 5 years, herbaceous control for 4 years, and total control after site preparation. This regionwide investigation is known as the Competition Omission Monitoring Project (COMB), a coordinated study with the Auburn University Silvicultural Herbicide Cooperative (Study HB-4F). Data summaries for each location are presented for loblolly pine growth and competition intensities for the first 8 years. Approximately 10,990 loblolly pine seedlings have been measured annually. Responses from this network of studies should be useful in assessing and reporting relative growth of loblolly pines for other studies and operational plantings. These data sets should be useful also for future forest growth modeling efforts.
