Service

Pacific Northwest
Research Station

The **Forest Service** of the U.S. Department of Agriculture is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives—as directed by Congress—to provide increasingly greater service to a growing Nation.

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, gender, religion, age, disability, political beliefs, sexual orientation, or marital or family status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD).

To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326-W, Whitten Building, 14th and Independence Avenue, SW, Washington, DC 20250-9410 or call (202) 720-5964 (voice and TDD). USDA is an equal opportunity provider and employer.

USDA is committed to making its information materials accessible to all USDA customers and employees.

Authors

Sally Campbell is a biological scientist, **Paul Dunham** is a forester, and **David Azuma** is a research forester, Forestry Sciences Laboratory, 620 SW Main, Suite 400, Portland, OR 97205.

Abstract

Campbell, Sally; Dunham, Paul; Azuma, David. 2004. Timber resource statistics for Oregon. Resour. Bull. PNW-RB-242. Portland, OR: U.S. Department of Agriculture, Forest Service, Pacific Northwest Research Station. 67 p.

This report is a summary of timber resource statistics for all ownerships in Oregon. Data were collected as part of several statewide multiresource inventories, including those conducted by the Pacific Northwest Region (Region 6) on National Forest System lands in Oregon, by the Bureau of Land Management (BLM) on BLM lands in western Oregon, and by the Pacific Northwest Research Station Forest Inventory and Analysis (FIA) Program on BLM lands in eastern Oregon and state and private lands across Oregon. Statistical tables provide estimates of land area, timber volume, growth, mortality, and harvest for the state and half-state units (western and eastern Oregon).

Keywords: Forest inventory, statistics (forest), timber resources, timberland, resources (forest), Oregon, western Oregon, eastern Oregon.

Summary

Oregon has an estimated 61 million acres of land. About 49 percent of this land is forested with 76 percent of the forested portion being nonreserved timberland. About 58 percent of the timberland is managed by national forests and other federal agencies, 4 percent is managed by state and local agencies, and 38 percent is privately owned. Douglas-fir is the most common forest type in western Oregon forests, and ponderosa pine is most common in eastern Oregon forests. Younger stands (0-60 years) predominate in western Oregon, and older stands (80-199 years) predominate in eastern Oregon. The net volume of growing stock on all timberland is 78 billion cubic feet, with 91 percent of this from softwoods (coniferous species). About 71 percent of the growing-stock volume is on public land, 19 percent on forest industry land, and 9 percent on other private land. Estimated net annual growth of sawtimber is 1,689 million cubic feet, estimated average annual mortality is 444 million cubic feet, and average annual removals are 1,045 million cubic feet (4,710 million board feet).

Introduction

This report summarizes the timber resource statistics for Oregon's forests. It uses data from forest inventories conducted in Oregon in the 1990s: the 1998–99 Pacific Northwest Forest Inventory and Analysis (PNW-FIA) inventory of eastern Oregon, the 1994–98 PNW-FIA inventory of western Oregon, the 1993–96 Pacific Northwest Region (Oregon and Washington national forests) inventory, and the 1997 Bureau of Land Management (BLM) inventory of western Oregon. Other resources sampled but not included in this report include understory vegetation, crown cover, insects, diseases, coarse woody material, and snags. These data will be analyzed and reported in other publications.

The PNW-FIA unit has been reporting statistics for Oregon since the 1930s. Bolsinger and Berger (1975), Farrenkopf (1982), Gedney et al. (1989), and Azuma et al. (2004b) reported inventory statistics in the 1960s, 1970s, 1980s, and 1990s, respectively, for eastern Oregon. Hazard and Metcalf (1964, 1965), Metcalf and Hazard (1964), Bassett (1977), Jacobs (1978), Mei (1979), Gedney et al. (1986a, 1986b, 1987), and Azuma et al. (2004a) reported inventory statistics in the 1960s, 1970s, 1980s, and 1990s

for western Oregon. Inventory and reports from the 1970s on did not include BLM land in western Oregon or any Oregon national forests. The current sampling system is a systematic grid of plots, established in the early 1960s by PNW-FIA for areas outside of national forests and in the 1990s by Pacific Northwest Region (Region 6) and BLM for national forests and western Oregon BLM land, respectively. Azuma et al. (2004a, 2004b) used 1999 and 1998 PNW-FIA data sets to report the latest forest statistics for eastern and western Oregon, respectively.

This report contains statistical tables that provide current estimates of forest land and timberland area (see “Glossary”), timber volume, growth, mortality, and harvest. The national forest statistics include areas that are withdrawn from timber production but still meet the FIA definition of timberland. National forest land is not all equally available for timber production owing to various management decisions (see “Reserved Area,” p. 8). Estimates of change in volume and area of nonfederal land between the 1980s and the present inventory are reported in Azuma 2004a and 2004b.

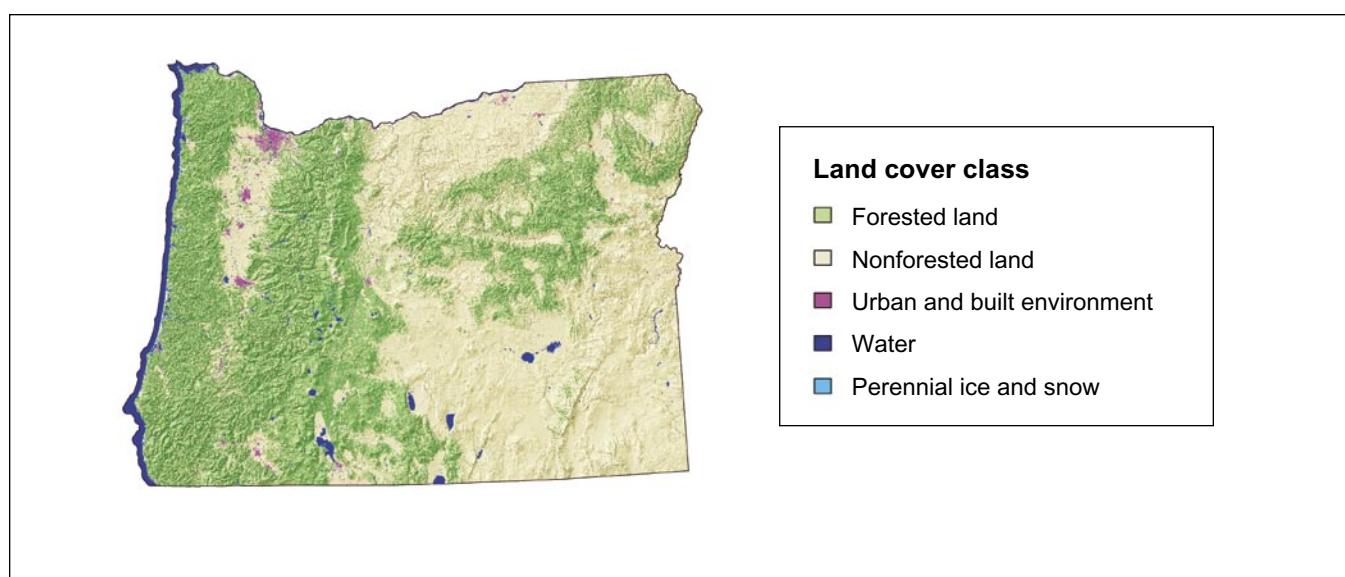

Figure 1—Forested land in Oregon. This map was developed by the USDA Forest Service, Pacific Northwest Research Station, Forest Inventory and Analysis Program (FIA), Portland, Oregon, by using U.S. Geological Survey (USGS) Multiresolution Land Characterization Consortium (MRLC) land cover classification data based on 1992 Landsat Thematic Mapper (TM) satellite imagery.

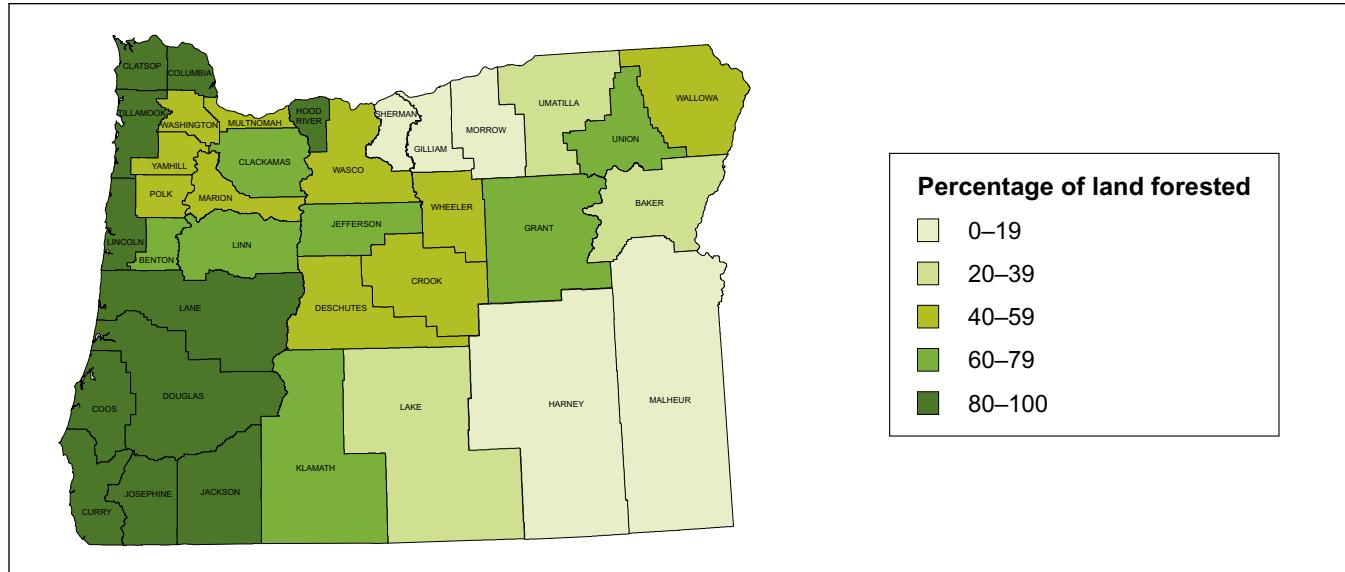

Figure 2—Percentage of land that is forested, by county, in Oregon. This map was developed by the USDA Forest Service, Pacific Northwest Research Station, Forest Inventory and Analysis Program (FIA), Portland, Oregon, by using area estimates from the 1993–99 inventories conducted by FIA, Region 6, and BLM.

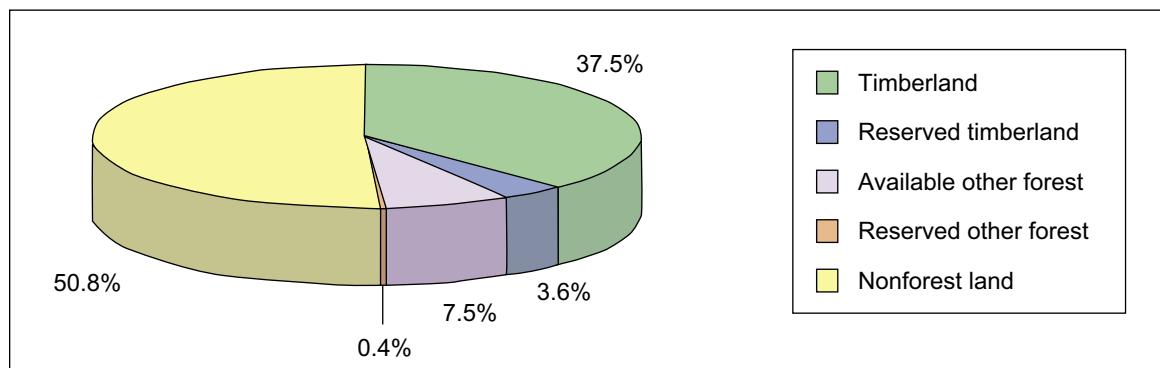

Figure 3—Land categories in Oregon, 1999.

Highlights

Forested Area

The state of Oregon encompasses over 61 million acres. About 49 percent of the area is forest land; of this, 76 percent is nonreserved timberland (figs. 1–3, app. table 1). Western Oregon (from the crest of the Cascade Range west to the Pacific Ocean) has 15.4 million acres of forest land with 87 percent of it classed as nonreserved timberland, and eastern Oregon (from the crest of the Cascade Range to the eastern border of the state) has 14.8 million acres with 65 percent nonreserved timberland. Eastern Oregon forest land

includes about 2 million acres of juniper forest land surveyed in the 1980s (Gedney et al. 1999)

Forest Land Ownership

The National Forest System (NFS), the BLM, and other federal agencies manage about 59 percent of the forest land (58 percent of the timberland) in Oregon. Owners classed as forest industry manage about 21 percent of the forest land (25 percent of the timberland); nonindustrial private owners and other public owners manage about 16 and 4 percent of forest land (13 and 4 percent of timberland), respectively. See figures 4 and 5, and appendix tables 2, 3, and 5.

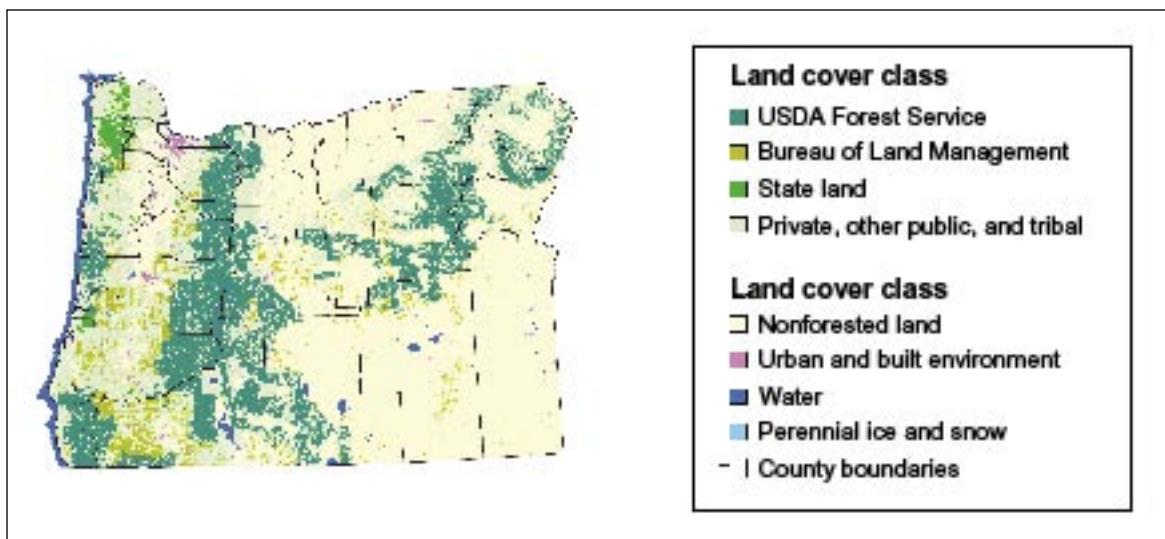

Figure 4—Ownership of forested land in Oregon. This map was developed by the USDA Forest Service, Pacific Northwest Research Station, Forest Inventory and Analysis Program (FIA), Portland, Oregon, by using U.S. Geological Survey (USGS) Multiresolution Land Characterization Consortium (MRLC) land cover classification data based on 1992 Landsat Thematic Mapper (TM) satellite imagery and land ownership information derived from the Gap Analysis Project (GAP).

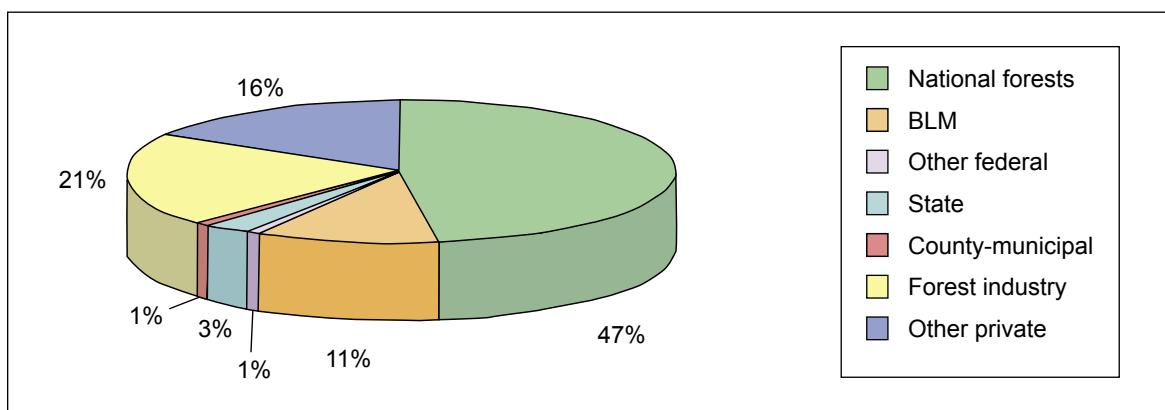

Figure 5—Forest land by owner, Oregon, 1999.

Forest Type

Forest type refers to the dominant tree species in a stand. The majority of Oregon forest land (and timberland) is dominated by softwood forest types (83 percent), with Douglas-fir the most abundant type in western Oregon and ponderosa pine in eastern Oregon (fig. 6). Appendix tables 3 and 4 display forest land area by forest type and owner and stand size; tables 6, 7, and 9 display timberland area by forest type and owner, age, and stand size, respectively.

Timberland Stand Age

Stand age classes are fairly evenly distributed on timberland across the state as a whole. However, age distributions in western and eastern Oregon are quite different, with younger stands (0–60 years) predominant in western Oregon and older stands (80–199 years) predominant in eastern Oregon (fig. 7). Appendix tables 7 and 8 display timberland area by stand age and forest type, and by stand age and owner, respectively.

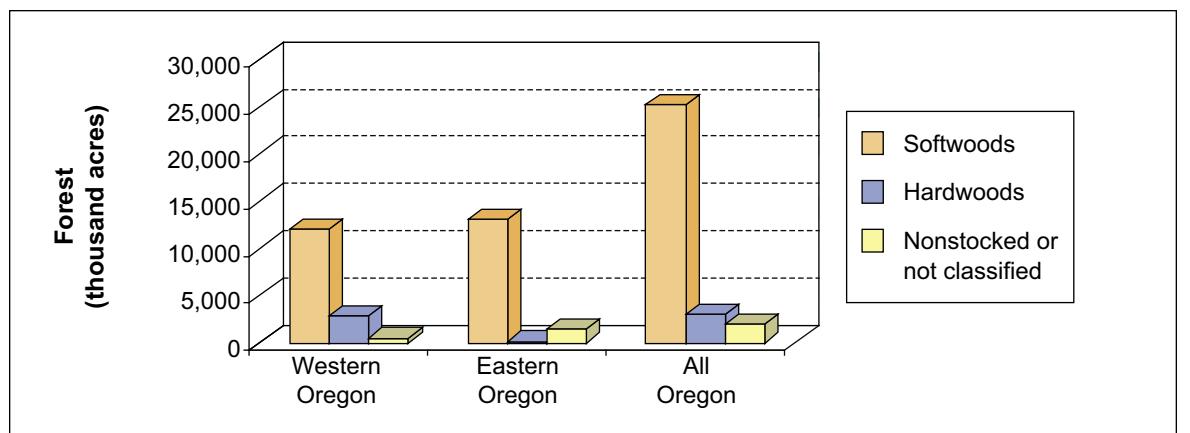

Figure 6—Forest land area by forest type groups, Oregon, 1999.

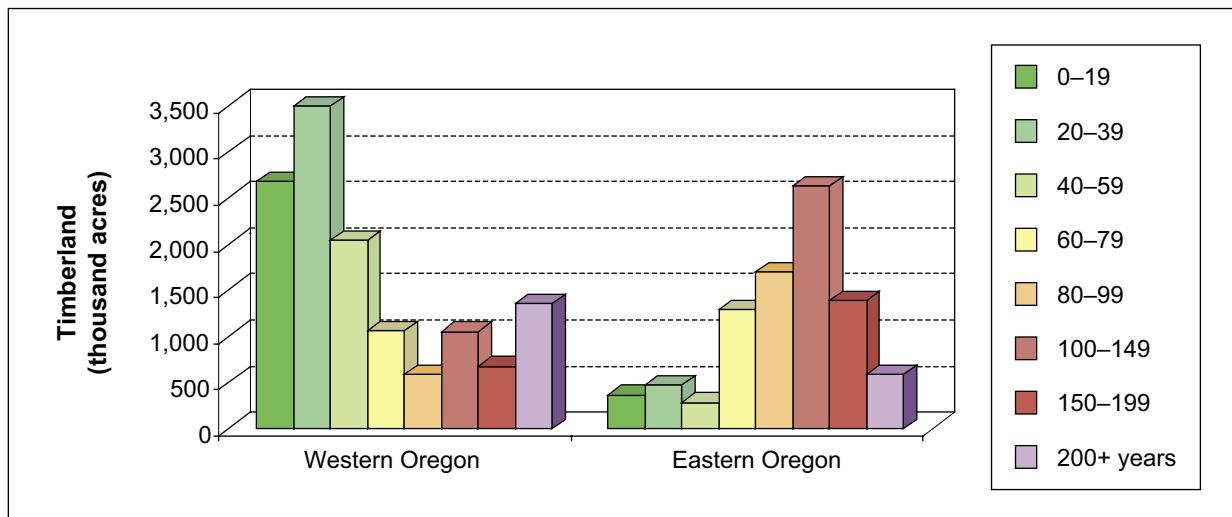

Figure 7—Timberland (nonreserved) area by stand age class, Oregon, 1999.

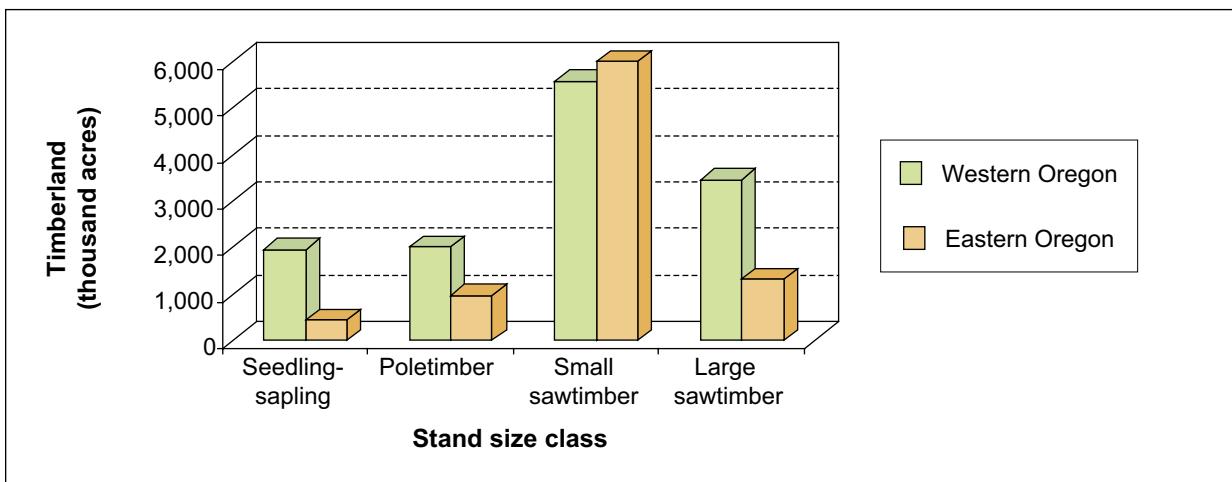

Figure 8—Timberland (nonreserved) area by stand size class, Oregon, 1999.

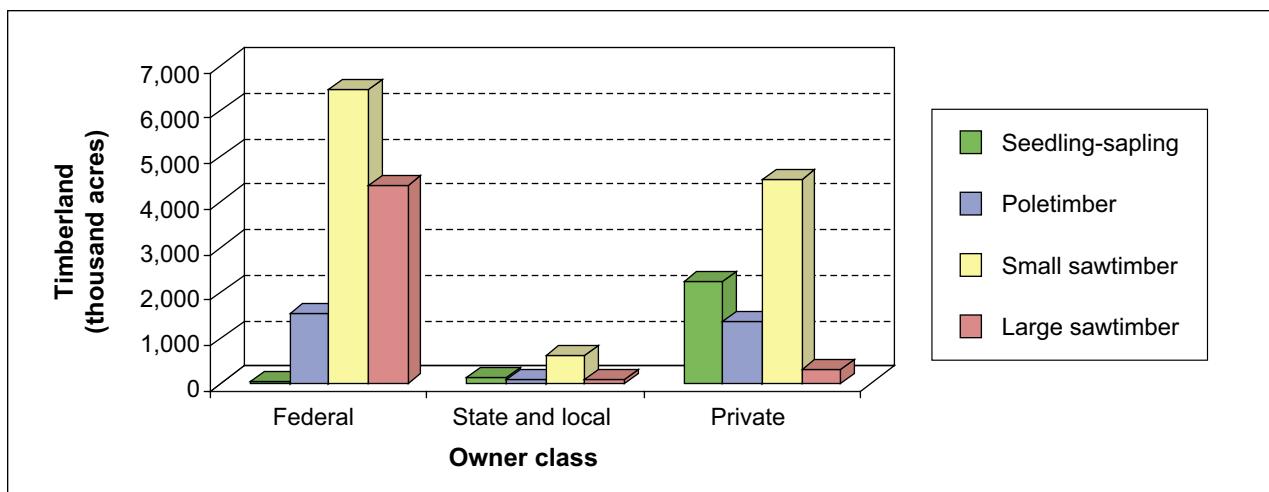

Figure 9—Timberland (nonreserved) area by stand size and owner class, Oregon, 1999.

Timberland Stand Size

Statewide, the majority (71 percent) of timberland is in the small and large sawtimber classes (average stand diameter at breast height [d.b.h.] 9–21 inches and greater than 21 inches, respectively) (fig. 8). Nonfederal timberland tends to be skewed to the small size classes and federal timberland to the larger size classes (Azuma et al. 2004a, 2004b) (fig. 9). Small sawtimber stands account for 62 percent of all sawtimber stands in western Oregon and 82 percent of sawtimber stands in eastern Oregon. Appendix tables 9 and 10 display timberland area by stand size class and forest type, and by stand size class and owner, respectively.

Timberland Productivity

Potential productivity of forest land can be expressed as productivity site classes (app. table 11; figs. 10 and 11). Federal timberland has the greatest percentage of acres in lower site classes statewide. In western Oregon, state timberland has 91 percent in the higher classes (>120 cubic feet per acre per year) and private timberland has 75 percent. In eastern Oregon, most acres are in the lower productivity classes (<120 cubic feet per acre per year).

Timberland Volume

Volume of poletimber (5–9 inches d.b.h. for softwoods and 11 inches d.b.h. for hardwoods) and sawtimber (over 9 inches

d.b.h. for softwoods and 11 inches d.b.h. for hardwoods) across all owners, statewide, and excluding cull volume, is over 77 billion cubic feet (fig. 12). Ninety-one percent of this volume is from softwoods and 9 percent from hardwoods. Cull volume is about 3 billion cubic feet. Appendix table 12 displays timber volume by timber class (sound or cull), tree size class, and species group, and table 13 displays timber volume by forest type and stand size class.

The majority of growing-stock volume on Oregon's timberlands is on national forests (52 percent), followed by forest industry (19 percent), BLM (13 percent), other private forest land (10 percent), and other public land (6 percent) (fig. 13). Appendix table 14 displays timberland growing-stock volume by owner and species group.

Timberland Growth, Mortality, and Removals

From the 1980s to the 1990s, growth exceeded mortality for all owners across all forest types, statewide, resulting in positive net growth for growing-stock trees (app. table 15). A few forest types, such as mountain and western hemlock, in eastern Oregon on some ownerships showed greater mortality than growth. For sawtimber, when removals are factored in, the volume of growth is greater than the volume of mortality plus harvest removals for public owners but not for private owners statewide (app. table 16, fig. 14). This is reflected in the ratio of current gross annual growth to the

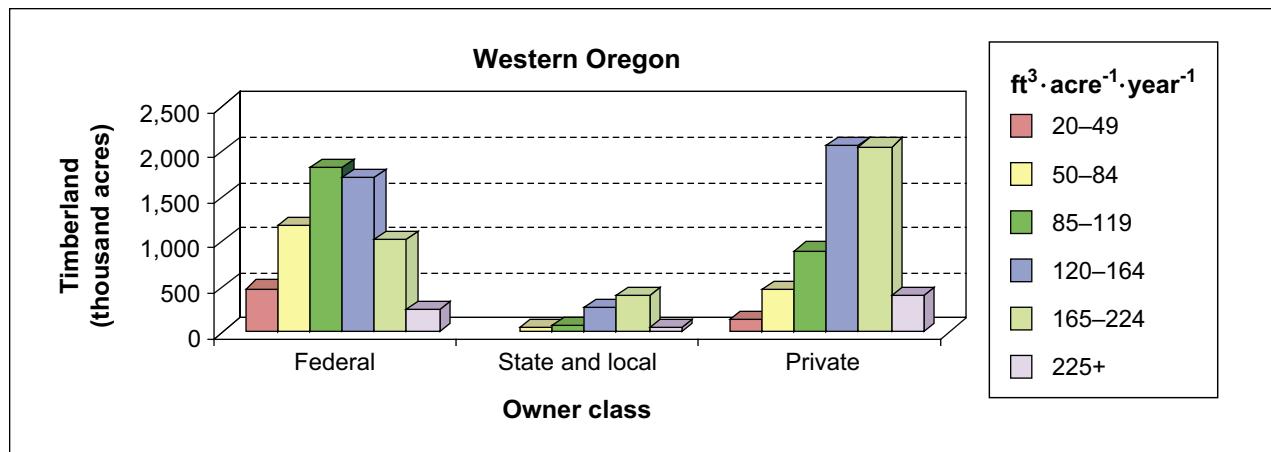

Figure 10—Timberland (nonreserved) area by site classes (mean annual increment), western Oregon, 1999.

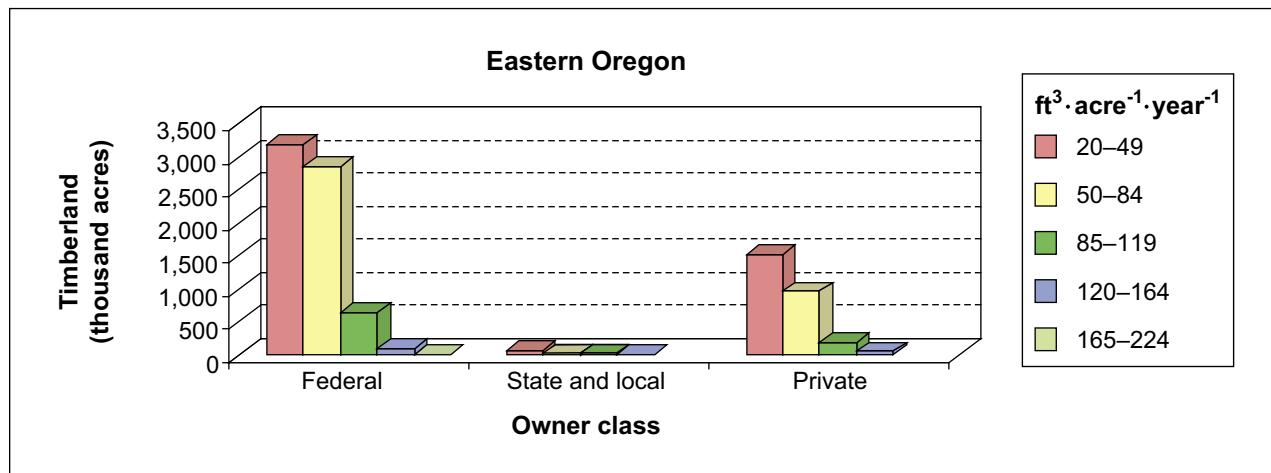

Figure 11—Timberland (nonreserved) area by site classes (mean annual increment), eastern Oregon, 1999.

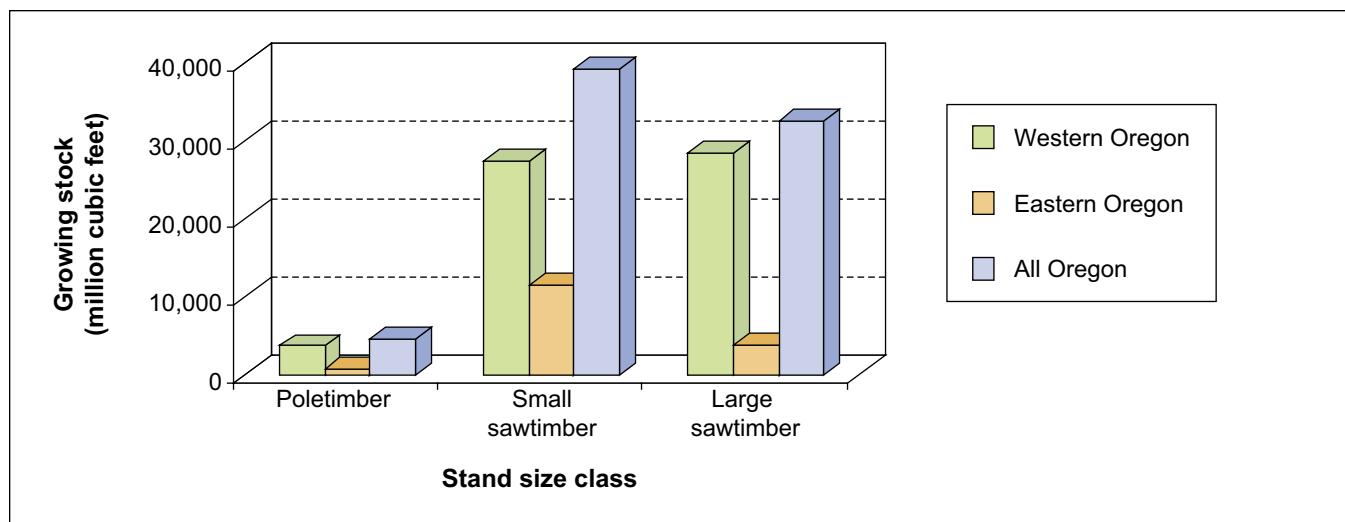

Figure 12—Volume of growing stock on nonreserved timberland by stand size class, Oregon, 1999.

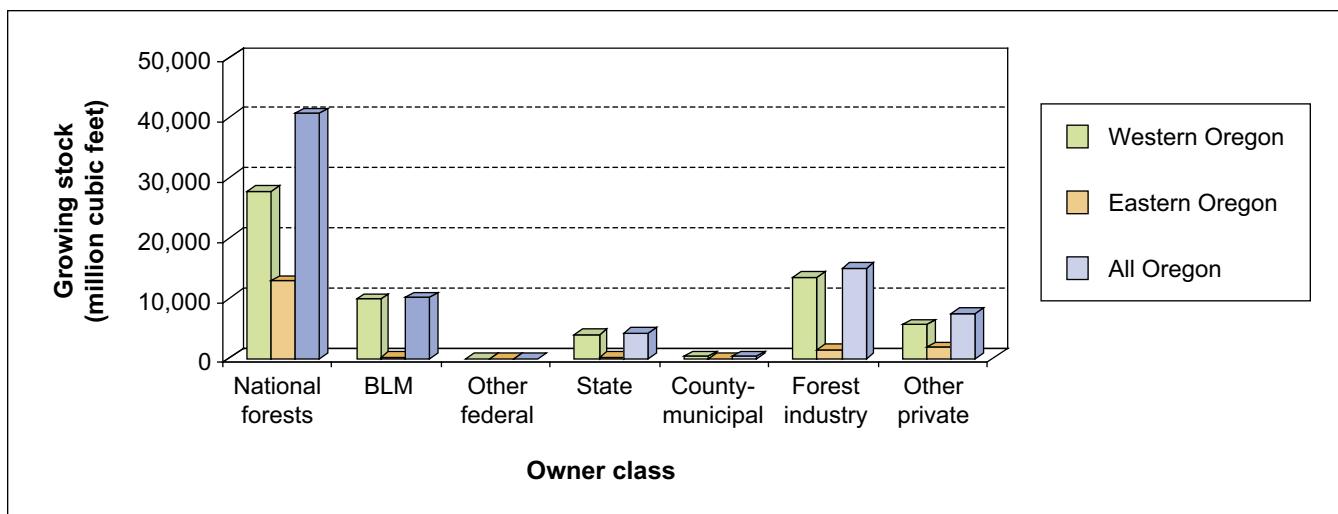

Figure 13—Volume of growing stock on nonreserved timberland by owner class, Oregon, 1999.

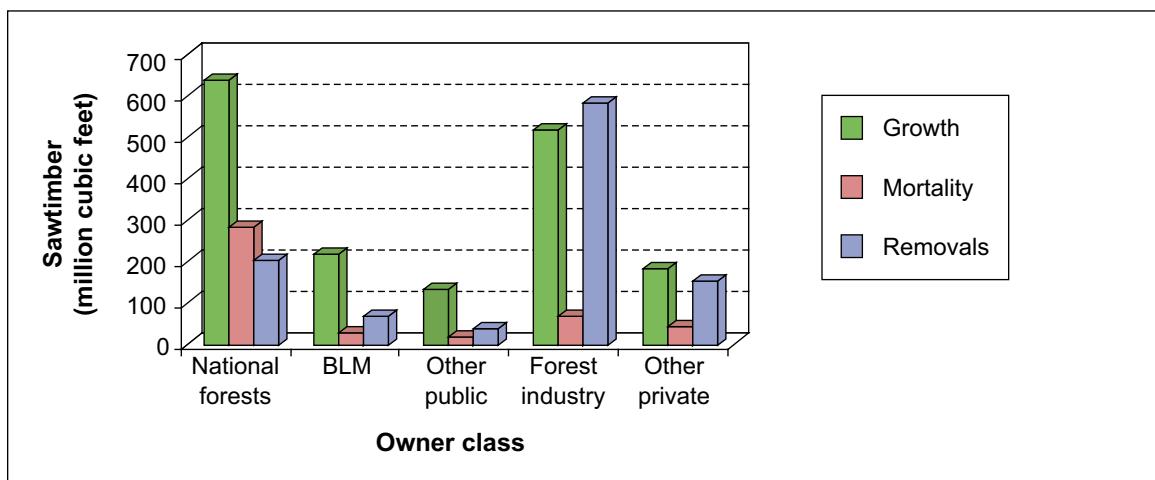

Figure 14—Sawtimber growth (current gross annual), mortality (average annual), and harvest (average annual) on nonreserved timberland by owner class, Oregon, 1990s.

sum of average annual mortality and average annual removals where values less than 1.0 indicate that mortality and removals exceed growth (fig. 15).

The production of timber has shifted away from federal land to state and privately owned land over the last three decades (fig. 16, app. table 17). In the 1980s, federal land in **western Oregon** had an annual average harvest of 2,667 million board feet. In the 1990s that number dropped to 685 million board feet per year. Other public and private land averaged 3,046 million board feet per year in the 1980s

and decreased 8 percent to 2,807 million board feet in the 1990s. The 74-percent reduction from federal land does not represent a change in land class, but is evidence of changing availability of land for timber production based on new management decisions. Federal land areas with reduced availability include, but are not limited to, riparian reserves, wildlife reserves, and access-limited areas.

In eastern Oregon, from 1980 to 1989, timber harvest volume from federal land averaged 1,205 million board feet per year. That number dropped to 530 million per year

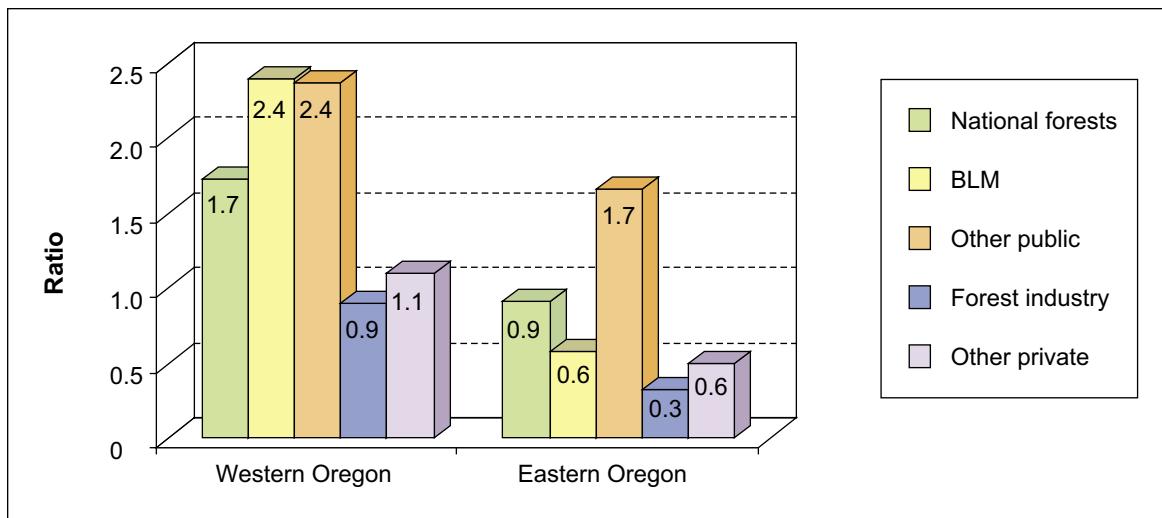

Figure 15—Ratio of growth (current gross annual) to the sum of mortality (average annual) and removals (average annual) for sawtimber on nonreserved timberland by owner class, Oregon, 1990s.

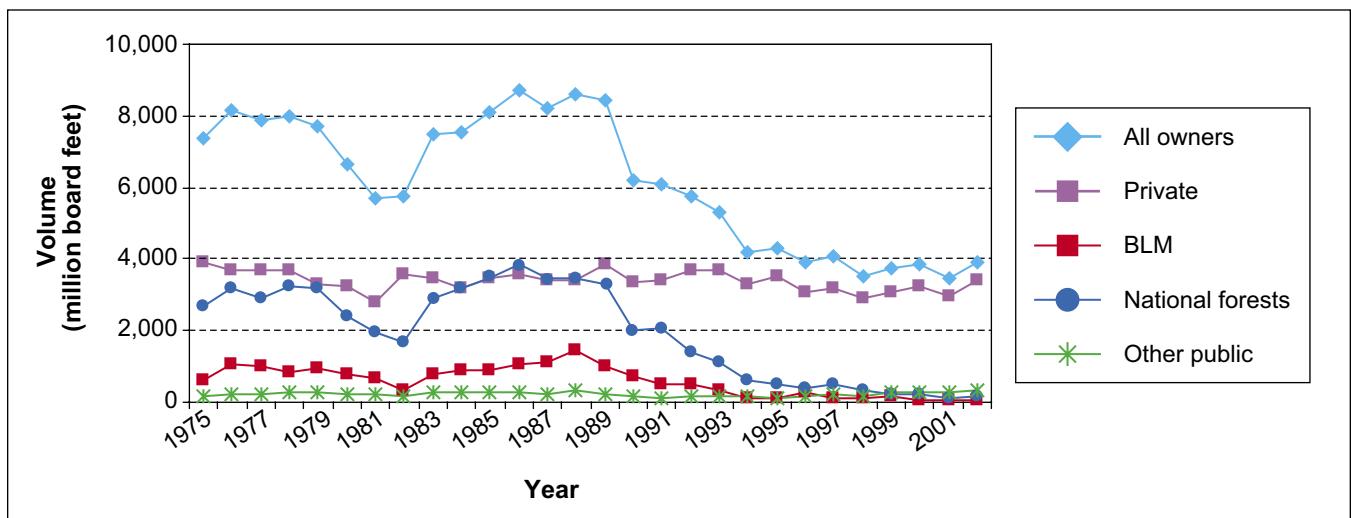

Figure 16—Harvest volume by owner class, Oregon, 1975–2002 (from Oregon Department of Forestry 2003).

between 1990 and 1999, a decrease of 56 percent from the 1980s. Other public and private land, composing only 29 percent of the timberland in eastern Oregon, produced on average, 33 percent of the harvest volume per year in the 1980s (604 million board feet), and 56 percent from 1990 to 2000 (688 million board feet).

Reserved Area

Figures 17 and 18 show area of timberland and volume of timber on that land based on two different reserve classification systems: the FIA classification where reserved lands are

defined as those reserved through statute, ordinance, or administrative order; and the Oregon Department of Forestry (ODF) classification (Herstrom et al. 2003), which classifies forest land into reserved, multiresource (with restricted timber harvest), and active categories (see app. 1 for a description of these categories; see also tables 19 and 20).

In addition to land officially designated as reserved, another 12 percent of the forest land in Oregon is currently not available for timber harvest (Herstrom et al. 2003). This land includes state and county parks, Nature Conservancy land, and a number of categories on national forests such

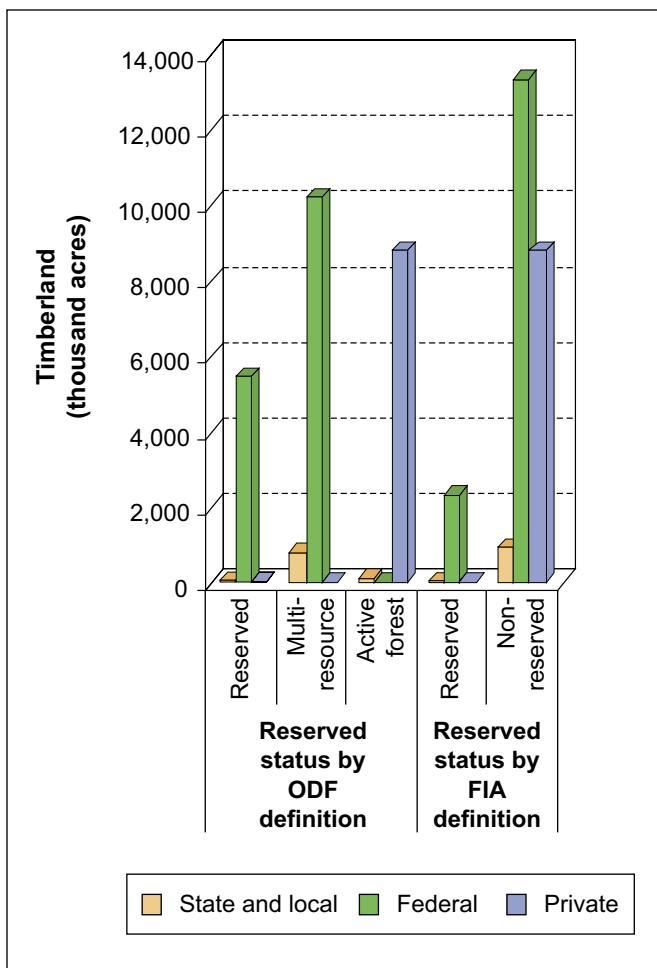

Figure 17—Estimated area of timberland, by reserve status and owner class, Oregon, 1999.

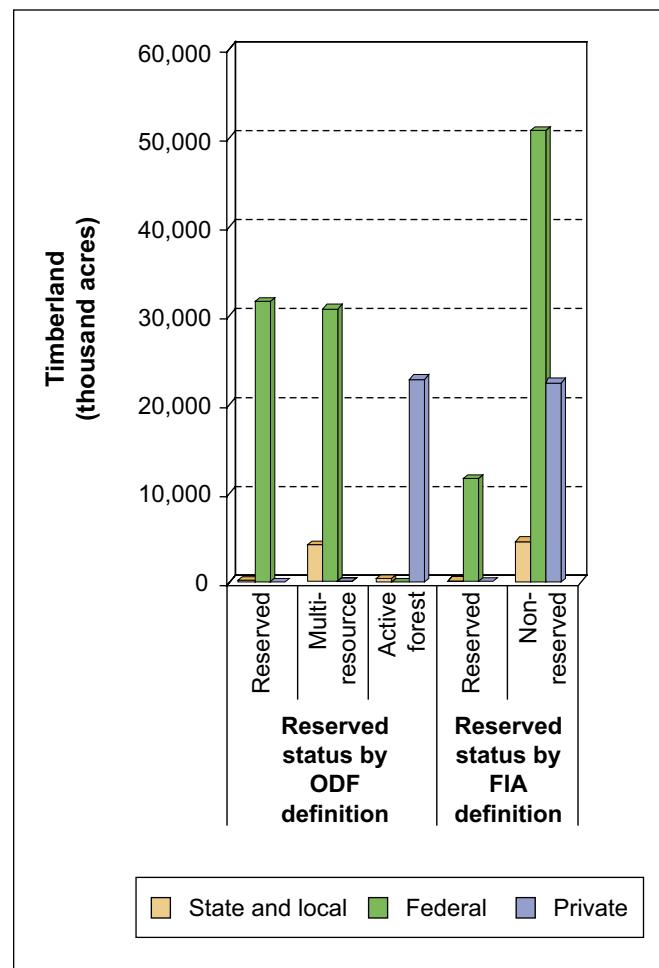

Figure 18—Estimated timber volume on timberland, by reserve status and owner class, Oregon, 1999.

as late-successional reserves, riparian areas, and research natural areas. Current regulations allow some timber harvesting on additional land (42 percent of forest land) but also include restrictions for wildlife habitat or other uses (Herstrom et al. 2003). Revisions of national forest plans, state laws, and other agency policies could result in changes in timber production locations and acres.

All of the reserved and multiresource area is managed by the Forest Service and other public entities (table 19). Site productivity tends to be higher on active forest land, with 25 percent in site classes of 165 or more cubic feet per acre per year compared to reserved and multiresource forest land with only 10 percent in the classes of 165 or more cubic feet per acre per year (app. table 18).

Inventory Procedures

Oregon was inventoried by using double sampling for stratification (Cochran 1977) for the nonfederal lands and a simple stratified random sample for NFS and BLM lands. The sampling was implemented on a permanent systematic grid producing an even geographic distribution of secondary (field) plots across the state. The primary sample used on the nonfederal lands consists of photo plots placed at random inside each square of the grid.

The primary sample for nonfederal lands was a grid of nearly 70,000 points established in 1987 by using aerial photography from 1982 with some updates from 1994 for eastern Oregon and 24,000 points established in 1994 for western Oregon. Data collected on each point included, but

were not limited to, land use, owner, plant community, and stage of development. For coniferous stands, percentage of crown cover and a height code also were collected. The primary sample is used for the stratification of the secondary sample points to increase the precision of estimates.

The secondary sample consisted of 4,378 forest and nonforest field locations established in previous inventories and remeasured or reclassified in the 1998–99 period for eastern Oregon and 1,478 forest and nonforest field locations established in previous inventories and remeasured or reclassified in the 1994–98 period for western Oregon. This sample represents about a 1-in-16 subsample of the primary sample. The national forest plots were taken on a similar grid system with a different plot design (Max et al. 1996). The data were collected for these inventories between 1993 and 1996 and are in the 1997 Resources Planning Act (RPA) database.

The 1998 eastern Oregon PNW-FIA inventory also included reserved lands, which were excluded from previous PNW-FIA inventories. The major addition is from Crater Lake National Park with about 220,000 acres.

In the previous PNW-FIA inventories in the 1980s, a cluster of five subplots covering an area of about 8 acres was installed at timberland grid locations. At that time, the cluster of subplots sampled a single homogeneous condition, by moving subplots into the condition if necessary. At each subplot, variable-radius sampling was used to select trees over 5 inches d.b.h., and a fixed-radius plot was used to sample seedlings and saplings.

In the 1990s PNW-FIA inventories, the sampling design was modified to remove potential bias inherent in the 1980s procedures. The term “condition class” was defined for the modified design to identify different situations that could occur on a plot. A condition class, or “condition,” refers to an area with a distinct land class (timberland, woodland, nonforest, etc.) and vegetative condition (forest type, stand age, etc.). The modified design requires that all subplots for a cluster (the plot) remain fixed. For plots that straddle two or more conditions, we now sample all conditions by mapping the boundaries around each condition, essentially subdividing the plot. The information pertinent to each condition was recorded as condition class attributes. When

multiple conditions exist on a plot, all data in one condition are processed together. This can affect the amount of information available for classifying stand characteristics, such as forest type, stand size, and stand age. For example, on 7,014 secondary sample locations outside of national forest land in the 1990s Oregon PNW-FIA inventory, 7,524 condition classes were sampled, of which 1,951 were timberland conditions. On the 1,637 plots that contained a timberland condition, roads were the most common nonforest condition followed by grassland steppe or high desert shrub land.

Small differences in acreage and volume estimates in different publications summarizing data from these inventories (Oregon 1990s periodic inventories) are due to use of different versions of the inventory database. The tables in this report are compiled from the PNW-FIA integrated database version 1.4 (2004).

Land and Water Area Updated

The Bureau of the Census compiles and publishes the area of land and water in the United States every 10 years. These area figures, available by state and county, are accepted and used by PNW-FIA in Portland as the gross number of acres to be inventoried in each county. The previous inventory was based on 1980 census data, and the current inventory uses 1990 census figures. Raster-scanned U.S. Geological Survey topographic maps and a geographic information system are now used by the Bureau of the Census to identify water bodies and landforms and to determine the size of areas much smaller than was possible previously. As a result, the definition of inland water was changed to reflect the finer resolution: streams with a minimum width of 200 feet are now recognized, compared to 660 feet in 1980, and small water bodies are now at least 4.5 acres, compared to 40 acres in the past.

Changes in Ownership Definitions

Land owned by Native Americans is now classified as “other private.” In the 1980s inventories, these lands were defined as “other public.” Forest industry is no longer divided into two categories: “forest industry with mills” or “forest industry without mills;” instead both are now classed as forest industry.

Reliability of Inventory Data

Inventories are designed to provide sampling errors consistent with national standards set by the USDA Forest Service. The target sampling errors for total timberland area is 3 percent for one million acres and 10 percent for one billion cubic feet of growing-stock volume. The sample design for this inventory provides the highest precision when estimates are aggregated for the entire state. As the sample is divided into smaller units, the confidence intervals (standard errors) increase as a proportion of the estimate. Confidence intervals are quantitative expressions of the variability inherent in the sampling and estimation procedures. Most of the tables in this report show standard errors for the major categories of displayed data.

Glossary

available other forest land—Forest land available for harvest but incapable of growing 20 cubic feet per acre per year (mean annual increment at culmination in fully stocked, natural stands) of industrial wood because of adverse conditions such as sterile soils, dry climate, poor drainage, subalpine sites, steepness, or rockiness.

condition class—A mapped area on a plot with a distinct land class (e.g., timberland, oak woodland, nonforest) or a distinct vegetative condition (e.g., forest type, stand size). The condition identified at plot center is the only condition that is remeasured and used for the analysis of periodic change.

cull trees—Live trees of noncommercial species, and live trees of commercial species that are more than 75 percent defective. Noncommercial species are junipers, Pacific yew, Pacific dogwood, apple, and willow. Cull trees are not growing-stock trees.

cull trees, rotten—Cull trees with defect caused primarily by rot.

cull trees, sound—Trees of noncommercial species or cull trees of commercial species with defect caused primarily by poor form and roughness.

diameter class—A classification of trees based on diameter outside the bark measured at breast height, 4½ feet above

the ground. The common abbreviation for diameter at breast height is d.b.h. Trees are grouped into 2-inch classes up to 21 inches d.b.h., after which the class intervals become broader.

forest industry land—Land owned by companies that grow timber for industrial use. Includes companies both with and without wood processing plants.

forest land—Land at least 10 percent stocked with live trees, or land that had this minimum tree stocking in the past; is not currently developed for nonforest use; and is larger than one acre and at least 120 feet wide.

forest types—Stands are classified as pure softwood, pure hardwood, softwood-hardwood mix, or hardwood-softwood mix. Stands with 70 percent or more of the stocking in live softwood trees are classified as pure softwood types and are assigned the type name of the softwood species with the greatest stocking among all softwoods on the condition class plot. Stands with 70 percent or more of the stocking in live hardwood trees are classified as pure hardwood types and are assigned the type name of the hardwood species with the greatest stocking among all hardwoods on the condition class plot. Mixed species types are assigned if softwood stocking is from 31 to 69 percent total stocking on the plot: stands with 50 to 69 percent of the stocking in live softwood trees are classed as softwood-hardwood types and receive a type name that includes the softwood species with the greatest softwood stocking followed by the hardwood species with the greatest hardwood stocking; stands with 51 to 69 percent of the stocking in live hardwood trees are classed as hardwood-softwood types and receive a type name that includes the hardwood species with the greatest hardwood stocking followed by the softwood species with the greatest softwood stocking. For ease in reporting, the secondary forest type will be identified after a slash as “softwood” or “hardwood” in the summary tables.

growing-stock growth, current net annual—The increase in growing-stock volume on timberland during the last year of the period between the previous and current inventories. Components of current net annual growth for growing-stock volume include (a) the increment in net volume of poletimber

and sawtimber growing-stock trees alive at the beginning of the year and surviving to year end; plus (b) ingrowth, the net volume of growing-stock trees reaching poletimber or sawtimber size during the year; minus (c) mortality, the net volume of poletimber and sawtimber growing-stock trees that died during the year.

growing-stock growth, periodic gross—The increase in growing-stock volume between the previous and current inventories that is attributable to increasing tree size. Periodic gross growth includes (a) the increment in net volume of poletimber and sawtimber growing-stock trees alive at both the previous and current inventories; (b) the increment in net volume of poletimber and sawtimber growing-stock trees alive at the previous inventory and harvested between inventories; and (c) ingrowth, the net volume of growing-stock trees reaching poletimber or sawtimber size between inventories.

growing-stock mortality, average annual—The annual net volume of poletimber and sawtimber growing-stock trees that died between the previous and current inventories.

growing-stock trees—All live trees except cull trees (see “cull trees”).

growing-stock volume—Net volume in cubic feet of live sawtimber and poletimber growing-stock trees from the top of a stump 12 inches tall to a minimum 4-inch top (of central stem) inside the bark. Net volume is gross volume less deductions for rot and missing bole sections.

hardwoods—Nonconiferous trees, usually broadleaved. See “Names of Trees” for a list of hardwood species in this report.

industrial wood—All commercial roundwood products except fuelwood. Roundwood includes logs or bolts that are in straight sections at least 8 feet long for hardwoods and 12 feet long for softwoods.

land area—Area reported as land by the Bureau of the Census (U.S. Department of Commerce 1990). Total land area includes dry land and land temporarily or partially covered by water, such as marshes, swamps, and river flood

plains; streams, sloughs, and canals less than 200 feet wide; and lakes, reservoirs, and ponds smaller than 4.5 acres.

land class—A classification of land by major use. The minimum area for classification is 1 acre.

mean annual increment (MAI) at culmination—A measure of the productivity of forest land expressed as the average increase in timber volume (in cubic feet) per acre per year. For a given species and site index, the mean is based on the age at which the MAI culminates for fully stocked natural stands. The MAI is based on the site index of the plot.

national forest land—Federal land that has been designated by Executive order or statute as national forest or purchase units and other lands under the administration of the USDA Forest Service, including experimental areas and Bankhead-Jones Title III land.

net volume—Gross volume less deductions for sound and rotten defects. Growing-stock net volume is gross volume (in cubic feet) less deductions for rot and missing bole sections on poletimber and sawtimber growing-stock trees. Sawtimber net volume is gross volume (in board feet) less deductions for rot, sweep, crook, missing bole sections, and other defects that affect the use of sawtimber trees for lumber.

noncommercial species—A tree species not commonly used for industrial wood products: juniper, Pacific yew, Pacific dogwood, apple, and willow. Noncommercial species will not be included in growing-stock volume tables; however, if one or more of these species dominate on a plot, the forest type might be classified as a noncommercial species.

nonforest land—Land that has never supported forests or formerly was forested and currently is developed for non-forest uses. Included are lands used for agricultural crops, Christmas tree farms, cottonwood plantations, improved pasture, residential areas, city parks, constructed roads, operating railroads and their right-of-way clearings, powerline and pipeline clearings, streams more than 30 feet wide, and 1- to 40-acre areas of water classified by the USDC Bureau of the Census as land. If intermingled in forest areas, unimproved roads and other nonforest strips must be more than

120 feet wide, and clearings or other areas must be 1 acre or larger to qualify as nonforest land.

nonstocked area—Timberland less than 10 percent stocked with live trees. Recent clearcuts scheduled for planting are classified as nonstocked area.

other private land—Private land not owned by forest industry. Native American land, farmer-owned land, and miscellaneous private land are included.

other public land—Land administered by public agencies other than the USDA Forest Service and USDI Bureau of Land Management. Other public land does not include Native American land, which is included with other private land.

poletimber stands—Stands with a quadratic mean diameter (mean diameter weighted by basal area) from 5.0 to 9.0 inches at breast height if a softwood stand and from 5.0 to 11.0 inches at breast height if a hardwood stand.

poletimber trees—Live growing-stock trees of commercial species that are 5.0 inches in d.b.h. or larger but smaller than sawtimber trees.

reserved other forest—Forest land that is incapable of growing 20 cubic feet per acre per year (mean annual increment at culmination in fully stocked, natural stands) of industrial wood and has been dedicated to noncommodity use through statute, ordinance, or administrative order.

reserved timberland—Forest land that is capable of growing 20 cubic feet or more per acre per year (mean annual increment at culmination in fully stocked, natural stands) of industrial wood but has been dedicated to noncommodity use through statute, ordinance, or administrative order.

sapling and seedling stands—Stands with a quadratic mean diameter (mean diameter weighted by basal area) less than 5.0 inches at breast height.

sapling and seedling trees—Live trees of commercial species that are less than 5.0 inches in d.b.h. with a minimum height of 6.0 inches and that have no diseases, defects, or deformities likely to prevent their becoming poletimber trees. Saplings have a minimum diameter of 1.0 inch.

sawtimber stands—Stands with a quadratic mean diameter (mean diameter weighted by basal area) 9.0 inches and larger at breast height if a softwood stand and 11.0 inches and larger at breast height if a hardwood stand. Small sawtimber stands are sawtimber stands with a mean diameter (weighted by basal area) less than 21.0 inches at breast height. Large sawtimber stands are sawtimber stands that have a mean diameter 21.0 inches or larger at breast height. Different utilization standards (such as 7.0-inch diameter) would result in higher stand volumes.

sawtimber trees—Live softwood trees of commercial species at least 9.0 inches in d.b.h. and live hardwood trees of commercial species at least 11.0 inches in d.b.h. At least 25 percent of the board-foot volume in a sawtimber tree must be free from defect. Softwood trees must contain at least one 12-foot saw log with a top diameter of not less than 7 inches outside bark; hardwood trees must contain at least one 8-foot saw log with a top diameter of not less than 9 inches outside bark.

sawtimber volume—Net volume of sawtimber trees measured in board feet. Softwood volume is estimated from the top of a stump 12 inches tall up to a minimum 6-inch top diameter, inside bark, and hardwood volume is estimated from the top of a stump 12 inches tall up to a minimum 8-inch top diameter, inside bark. Net sawtimber volume equals gross volume less deduction for rot, sweep, crook, and other defects that affect use for lumber.

Scribner rule—The common board-foot log rule used locally to determine sawtimber volume. Scribner volume is estimated in terms of 32-foot logs in western Oregon and 16-foot logs in eastern Oregon for softwoods and hardwoods. See “sawtimber volume” for utilization limits.

site class—A classification of the potential productivity of forest land expressed as mean annual increment (MAI) of timber volume (in cubic feet) at culmination in fully stocked natural stands. Six classes in this report are based on a range of MAI values that were calculated on every plot.

site index—A measure of the productivity of forest land expressed as the average height of dominant and codominant trees at a specified age.

softwoods—Coniferous trees, usually evergreen, with needles or scalelike leaves. See “Names of Trees” for a list of softwood species in this report.

stand age—The 10-year age class that best characterizes the stand.

stand-size class—A classification of stands based on tree size. Stand-size classes are sawtimber, poletimber, and sapling-seedling stands.

state land—Land owned by states or administered by state agencies.

stocking—The degree of occupancy of land by trees, measured by basal area or number of trees by size and spacing, or both, compared to a stocking standard; that is, the basal area or number of trees, or both, required to fully use the growth potential of the land.

timber class—A classification of trees as growing stock, cull, and salvable dead. Growing-stock trees are divided into poletimber and sawtimber trees.

timber harvest—Volume of roundwood removed from forest land for products.

timber volume—Includes the net volume in cubic feet of poletimber and sawtimber trees and salvable dead sawtimber trees, and the net volume in cubic feet of cull trees of commercial species. Volume is measured from the top of a stump 12 inches tall to a minimum 4-inch top diameter, inside bark.

timberland—Forest land capable of growing 20 cubic feet or more per acre per year (mean annual increment at culmination in fully stocked, natural stands) of industrial wood; is not in a reserved status through removal of the area from timber use by statute, ordinance, or administrative order; is not in a withdrawn status where it is pending consideration for reserved status; and is not developed for nonforest uses. See also “reserved timberland.”

Names of Trees

Common name	Scientific name ¹
Softwoods:	
Douglas-fir	<i>Pseudotsuga menziesii</i> (Mirb.) Franco
Engelmann spruce	<i>Picea engelmannii</i> Parry ex Engelm.
Grand fir	<i>Abies grandis</i> (Dougl. ex D. Don) Lindl.
Incense-cedar	<i>Calocedrus decurrens</i> (Torr.) Florin.
Jeffrey pine	<i>Pinus jeffreyi</i> Grev. & Balf.
Knobcone pine	<i>Pinus attenuata</i> Lemm.
Lodgepole pine	<i>Pinus contorta</i> Dougl. ex Loud.
Mountain hemlock	<i>Tsuga mertensiana</i> (Bong.) Carr.
Noble fir	<i>Abies procera</i> Rehd.
Pacific silver fir	<i>Abies amabilis</i> Dougl. ex Forbes.
Pacific yew	<i>Taxus brevifolia</i> Nutt.
Ponderosa pine	<i>Pinus ponderosa</i> Dougl. ex Laws.
Port-Orford-cedar	<i>Chamaecyparis lawsoniana</i> (A. Murr.) Parl.
Redwood	<i>Sequoia sempervirens</i> (D. Don) Endl.
Scotch pine	<i>Pinus sylvestris</i> L.
Shasta red fir	<i>Abies magnifica</i> A. Murr.
Sitka spruce	<i>Picea sitchensis</i> (Bong.) Carr.
Subalpine fir	<i>Abies lasiocarpa</i> (Hook.) Nutt.
Sugar pine	<i>Pinus lambertiana</i> Dougl.
Western hemlock	<i>Tsuga heterophylla</i> (Raf.) Sarg.
Western juniper	<i>Juniperus occidentalis</i> Hook.
Western larch	<i>Larix occidentalis</i> Nutt.
Western redcedar	<i>Thuja plicata</i> Donn ex D. Don
Western white pine	<i>Pinus monticola</i> Dougl. ex D. Don
White fir	<i>Abies concolor</i> (Gord. & Glend.) Lindl. ex Hildebr.
Whitebark pine	<i>Pinus albicaulis</i> Engelm.
Hardwoods:	
Apple	<i>Pyrus</i> spp.
Bigleaf maple	<i>Acer macrophyllum</i> Pursh
Black cottonwood	<i>Populus trichocarpa</i> Torr. & Gray
California black oak	<i>Quercus kelloggii</i> Newb.
California-laurel	<i>Umbellularia californica</i> (Hook. & Arn.) Nutt.
Canyon live oak	<i>Quercus chrysolepis</i> Liebm.
Cherry	<i>Prunus</i> spp.
Golden (giant) chinkapin	<i>Castanopsis chrysophylla</i> (Dougl.) A. DC.
Oregon ash	<i>Fraxinus latifolia</i> Benth.
Oregon white oak	<i>Quercus garryana</i> Dougl. ex Hook.
Pacific madrone	<i>Arbutus menziesii</i> Pursh
Quaking aspen	<i>Populus tremuloides</i> Michx.
Red alder	<i>Alnus rubra</i> Bong.
Tanoak	<i>Lithocarpus densiflorus</i> (Hook. & Arn.) Rehd.
White alder	<i>Alnus rhombifolia</i> Nutt.
Willow	<i>Salix</i> spp.

¹Nomenclature per Little 1979.

Acknowledgments

Many people were involved in the collection of data and the design of the inventories. Special thanks go to FIA, Region 6, and BLM data collection staffs as well as to the many landowners who allowed field crews on their land to visit plots. We also are indebted to those who developed the integrated database from which we extracted the tables for this report: Karen Waddell, Bruce Hiserote, Carol Apple, and Jim Alegria. Additional thanks to Dale Weyermann and John Chase for producing the maps displayed in this report and to Erica Hanson and Jennifer Gomoll for formatting the statistical tables. And lastly, we greatly appreciate our reviewers: Andy Gray, Gary Lettman, Olaf Kuegler, and Brad Smith.

Metric Equivalents

1 foot = 0.3048 meter

1 inch = 2.54 centimeters

1 mile = 1.609 kilometers

1 acre = 0.405 hectare

1 board foot = 0.833 cubic feet

1 cubic foot = 0.0283 cubic meters

1 cubic foot per acre = 0.07 cubic meter per hectare

Appendix 1—Oregon Department of Forestry—Forest Land Management Classifications (from Herstrom et al. 2003)

1. **Nonforest**—land with <10 percent crown closure that has not previously been in forest use and has not been converted from forest to another use (Note: recent timber harvest units are forest land).
2. **Reserved forest** (Forest reserved for conservation and recreation)—includes land reserved from regularly scheduled timber harvest by law, regulation, or forest plan requirement. The primary purpose of the designation is to reserve the land for production of nontimber values. Forest management is used to produce wildlife, esthetic, or other values, and limited harvests may only be conducted when it will benefit those values (i.e., safety, maintaining wildlife habitat, etc.).

The reserved forest class includes administratively withdrawn areas, congressionally reserved areas (such as national monuments, national parks, national wildlife refuges, Steens Mountain Cooperative Management and Protection Area, wild and scenic areas, wild and scenic rivers, and wilderness areas), late-successional reserves, state and county parks, riparian reserves (federal), special areas (such as areas of critical environmental concern, botanical areas, ecological emphasis areas, outstanding natural areas, and research natural areas), The Nature Conservancy land, and wildlife areas.

3. **Multiresource forest** (forest with restricted timber management)—includes land where restrictions on timber harvesting have been implemented through forest plans, state laws, or agency policies. This includes portions of land within management allocations where scheduled timber harvest may occur, but where restrictions for wildlife habitat or other uses will significantly reduce timber outputs.

4. **Active forest** (actively managed for timber production)—includes lands where scheduled timber harvest may occur and where sustainable supplies of timber are anticipated. These forest lands are regulated through the Oregon land use planning laws to maintain the land in forest uses by restricting development and through the Oregon Forest Practices Act to protect soil, air, water, and wildlife resources by regulating commercial forest operations. The active forest class includes private land and other public land.

Federal Lands—Reserved and Multiresource (Restricted Timber Management) Categories

Adaptive management areas—landscape units designated to encourage the development and testing of innovative approaches to restoring and managing late-successional and old-growth forests.

Administratively withdrawn areas—land identified in forest or district plans that includes recreation and visual areas, back country, and other areas where management emphasis precludes scheduled timber harvests.

Congressionally reserved areas—normally preclude timber harvesting except where it is needed to preserve or enhance the values of the designations, which include national monuments, national parks, national wildlife refuges, Steens Mountain Cooperative Management and Protection Area, wild and scenic areas, wild and scenic rivers, and wilderness areas.

East-side “screens”—the interim management direction for east-side federal forests (i.e., late-successional and wildlife “screens”) designed to maintain future planning options concerning wildlife habitat associated with late and old structural stages, fish habitat, and old-forest abundance. The screens allow for some timber harvest, limited to thinnings or group or individual tree selection, in stands where old-forest conditions, either multistrata with large trees or single-stratum with large trees, are at or above historical range of variability and timber harvest is needed to maintain or enhance old-forest conditions.

Experimental forests—used predominantly for research on the management of watersheds, soils, and vegetation. In general, the forests are used to develop concepts and tools needed to predict effects of disturbance, land use, and climate change on ecosystem structure, function, and species.

Key watersheds—part of the aquatic strategy within the federal Northwest Forest Plan. The major focus of management within the watersheds is on maintenance and restoration of fish habitat. The land use designation is an overlay on all other allocations within the plan. It requires that no new roads be built within unroaded portions of the watersheds, that existing road system mileage be reduced, and that no timber harvesting be conducted without a watershed analysis.

Late-successional reserves—areas that have been designated in federal plans to protect and enhance conditions of late-successional and old-growth forest ecosystems. They are designed to serve as habitat for species that use these forests, such as the spotted owl. There is no timber harvest allowed in stands over 80 years of age. Thinning and other silvicultural activities are restricted to treatments that are beneficial to the creation of late-successional forest conditions.

Matrix land (federal)—federal land in western Oregon outside the other federally designated categories (congressionally reserved, late-successional reserves, adaptive management areas, administratively withdrawn, and riparian reserves). Most federal timber harvesting and other silvicultural activities will be conducted in the matrix subject to standards and guidelines that include protective buffers around certain wildlife habitats (e.g., spotted owl and marbled murrelet sites) and leave snags and green trees in harvest units. Green tree retention requirements include:

- In the Oregon Coast Range each 640-acre block is managed on a 150-year rotation. When an area within a block is cut, 12 to 18 green trees per acre (t.p.a.) are retained (16 to 25 t.p.a. on BLM lands south of Grants Pass). There must be 25 to 30 percent of each block in late-successional forest at any point in time.

- For all other lands in western Oregon at least 15 percent of the area associated with each cutting unit is retained with a goal of having 70 percent of the total leave area in aggregates of 0.2 to 1 hectare or more.

National grassland—the Crooked River National Grassland is managed to promote the development of grassland agriculture and sustained yield management of forage, fish, wildlife, timber, water, and recreation resources. Fuelwood cutting is allowed by permit only in juniper stands that are not designated as old growth.

National recreation areas—Vegetation is managed to promote the maintenance and restoration of native plant communities. Trees are cut only to meet nontimber management objectives including recreation and wildlife habitat maintenance.

National scenic area (Columbia Gorge)—protects and provides for the enhancement of the scenic, cultural, recreational, and natural resources of the Columbia River Gorge.

Riparian reserves (federal lands)—areas adjacent to both sides of a stream, lake, or wetland where timber harvesting is prohibited. The width of the reserves are as follows:

- Fish-bearing streams, lakes, and natural ponds—a distance equal to two site-potential trees or 300 feet (each side), whichever is greater.
- Permanently flowing non-fish-bearing streams, constructed ponds and reservoirs, and wetlands larger than 1 acre—a distance equal to one site-potential tree or 150 feet (each side), whichever is greater.
- Seasonally flowing or intermittent streams—a distance equal to 100 feet (each side).

Special areas (includes areas of critical environmental concern, botanical areas, ecological emphasis areas, outstanding natural areas, and research natural areas)—special area designation protects and provides interpretation of unique geological, biological, and cultural areas for education, scientific pursuits, and public enjoyment. These areas preserve, protect, or restore native species composition and ecological processes of biological communities. They are

available for short- or long-term scientific study, research, and education and serve as a baseline against which human impacts on natural systems can be measured. Uses are managed to prevent loss of outstanding values.

Private and Other Public Land— Multiresource (Restricted Timber Management) Categories

Habitat conservation plans—Nonfederal landowners who wish to conduct activities on their land that might incidentally harm (or “take”) a species listed as threatened or endangered must first obtain an incidental take permit from the U.S. Fish and Wildlife Service. To obtain a permit, the applicant must develop a habitat conservation plan designed to offset any harmful effects the proposed activity might have on the species.

Oregon scenic waterways program—The Oregon Parks and Recreation Department must be notified of certain activities (including cutting trees) proposed within $\frac{1}{4}$ mile of the bank of Oregon’s designated scenic waterways. The proposed uses or activities may not be started until the written notification is approved, or until 1 year after the notice is accepted. Within that period, the Parks Department employs a variety of tools to maintain the scenic value of the river.

Riparian management areas (RMA)—areas on private and state lands in eastern Oregon adjacent to both sides of a stream or lake where timber harvesting is restricted. In general, coniferous trees in amounts similar to mature forests must be retained in riparian management areas along streams. The width of the riparian management area differs depending on the size of the stream and whether fish are present or the stream is used as a domestic water supply. Riparian management area widths for streams are generally as follows:

- Large streams (about 24 or more feet wide) with fish—100 feet
- Medium streams (about 5 to 24 feet wide) with fish—70 feet
- Small streams (up to about 5 feet wide) with fish—50 feet
- Small streams with domestic water use—20 feet

- Small streams without fish or domestic water use—no retention

Timber harvesting is restricted along streams on state forests in northwest Oregon generally as follows:

- Large and medium streams, and small streams with fish—170 feet
- Small perennial streams without fish—170 feet
- Small intermittent streams—100 feet.

Timber harvesting is restricted near streams on the Elliott State Forest in southwest Oregon generally as follows:

- Perennial streams with fish—100 feet
- Intermittent streams with fish—75 feet
- Perennial streams without fish—50 feet

Significant wetlands—In wetlands and estuaries larger than 8 acres, half of the trees, by species, in each size class must be left after harvesting. These trees must include trees that border the wetland, contribute to bank stability, or are used by predatory birds for nesting and perching.

State forest plan restrictions—State forests in different regions have different harvest restrictions including:

- Northwest Oregon State Forests Management Plan is based on an approach called structure-based management. Structure-based management is designed to produce and maintain an array of forest stand structures across the landscape in a functional arrangement that provides timber revenue, habitat for native species, and healthy aquatic systems. Structure-based management goals include maintaining a proportion of the forest in a mix of stand types over time: 5 to 15 percent in regeneration types (i.e., seedlings, saplings, and herbs and shrubs), 10 to 20 percent in closed single-canopy types, 15 to 35 percent in understory reinitiation types (i.e., gap in tree canopy allows understory of shrubs and herbs), 20 to 30 percent in layered types (i.e., tree canopy of two or more layers with trees of 18 inches d.b.h.), and older forest types (i.e., a minimum of eight trees per acre at least 32 inches d.b.h. and multiple canopy layers).

- Elliott State Forest Habitat Conservation Plan uses a landscape approach to provide and maintain habitat for the northern spotted owl and the marbled murrelet. The forest is divided into 17 management basins that use a mix of 80- to 240-year rotations. Over time, from 13 to 66 percent of each management basin will be managed as nesting, roosting, and foraging habitat. In addition, 19 percent of the forest is designated as reserves.
- Eastern Oregon region. Selective harvesting is used in most of the eastern Oregon region's forests to maintain or improve uneven-aged stand structure. Even-age management is limited to stands where ecological conditions, insects, or diseases make selective harvesting less attractive.

State and county parks (includes state parks, state park land, city and county parks, and waysides)—Goals for Oregon state parks include having existing and future recreational uses coexist and complement natural, scenic, and cultural resources within the park. State parks are assessed to identify discrete areas and determine the levels of suitability of resource areas for recreational use in conjunction with the need to protect important resources from disturbance. These resources include vegetation, wildlife habitat, protected species, water features and hazards, wetlands, and historical resources. Each of these resources is classified with respect to resource suitability based on criteria including current resource conditions, types, sensitivity, rareness, and extent of existing development or other intrusions. Areas with resources that are very sensitive or rare, even though they may be in good condition, have a very low tolerance for intensive, public, recreational uses and facilities development and typically are assigned a low suitability level for recreational development.

State research forests—The forests are used predominantly for teaching and research. They provide an array of education and research opportunities to advance societal awareness and participation in sound forest stewardship while providing sustainable financial resources to meet these needs. Forests are used for a variety of teaching and research

projects that include studies in silviculture, engineering, ecology, recreation, wildlife, cultural resources, and other subjects.

The Nature Conservancy land—The Nature Conservancy's mission is to preserve the plants, animals, and natural communities that represent the diversity of life on Earth by protecting the land and water they need to survive. The Nature Conservancy's vision is to conserve a set of places that, if managed appropriately, will ensure the long-term survival of all their native life and natural communities.

State wildlife areas (game management areas, game reserves, wildlife areas, and osprey management areas)—The State Wildlife Commission's goals are to:

- Maintain all species of wildlife at optimum levels.
- Develop and manage the land and water in a manner that will enhance the production and public enjoyment of wildlife.

Land is managed to prevent serious depletion of any indigenous species and to provide the optimum recreational and aesthetic benefits. Management practices affecting forage removal are established to protect the property and benefit wildlife resources.

Table 1—Estimated area, by county, land class, and administrative status, Oregon, 1999^a

County	Forest land					Nonforest land	All land ^c
	Available timberland	Reserved timberland	Available ^b other forest	Reserved other forest	Total

— = less than 500 cubic feet, or the equivalent in board feet, found.

^aTotals may be off because of rounding; data subject to sampling error.

^bIncludes softwood trees 9.0 inches in diameter at breast height and larger and hardwood trees 11.0 inches in diameter at breast height and larger.

^cRemovals calculated from removal data between 1990 and 1999. Source: Oregon timber harvest reports, Oregon Department of Forestry (ODF).

^dRemovals measured in board feet Scribner log scale; used ODF conversion factors to convert to cubic feet.

^eFor confidentiality reasons, Native American lands are included within the "Other private" group when summarizing at regional level.
