INTRODUCTION

Global digital data bases on the distribution and environmental characteristics of natural wetlands, compiled by Matthews and Fung (1987), have been archived on tape. These data bases were developed to evaluate the role of wetlands in the annual emission of methane from terrestrial sources. Five global 1° latitude by 1° longitude arrays are included on the tape. They are: (1) wetland data source, (2) wetland type, (3) fractional inundation, (4) vegetation type and (5) soil type. The first three data bases on wetland locations were published by Matthews and Fung (1987). The last two arrays contain ancillary information about these wetland locations: vegetation type from the data of Matthews (1983) and soil type from the data of Zobler (1986). This short paper is designed only to document the tape, and briefly explain the data sets and their initial application to estimating the annual emission of methane from natural wetlands. For complete discussions of the data, including sources and uncertainties, consult original publications listed in the references.

Globally, wetlands occur in a total of 3233 1° cells and occupy about $5.3 \times 10^{12} \text{m}^2$ (Matthews and Fung 1987). Each of the five data bases here includes information for the 3233 wetland locations; cells of other (non-wet) land and water are masked with unique values.

The outline below gives information about array characteristics such as dimensions, read formats, record lengths, block sizes and value ranges. Sections 1–5 following the outline contain descriptions and translation tables of the individual data bases. The final section includes information on the first calculation of global methane emission from natural wetlands done by Matthews and Fung (1987) using these data sets in conjunction with field measurements of methane fluxes from various ecosystems and simple latitudinal estimates about the seasonality of methane production.

The tape: 9 track, 1600 bpi, ASCII, BLP, RECFM=F

The arrays: record length = 1440, blocksize = 1440.
 (i,j) arrays are (360,180), 1° (lon,lat) resolution
 j = 1,180: j = 1: 1° band from 90°S to 89°S ...
 j = 180: 1° band from 89°N to 90°N
 i = 1,360: i = 1: 1° band from 180° (dateline) to 179°W ...
 i = 360: 1° band from 179°E to 180° (dateline)

Section 1. DATA SOURCES

Description: ISRC

The array of data sources (ISRC) gives information on the source or combination of sources for wetland designations. The three independent data sources integrated to produce the final data base are: (1) vegetation (Matthews 1983) classified with the UNESCO (1973) system (reference UNESCO in Table 1); (2) ponded soils from the data base of Zobler (1986) based on FAO soil maps (reference FAO); and (3) fractional inundation compiled specifically for the Matthews and Fung (1987) study of methane emission from wetlands based on a global series of 1:1M scale Operation Navigation Charts (reference ONC). All cells identified as wetland by any single source or combination of sources are designated as wetlands in the integrated data set given here. The three data sources provide a total of seven source combinations as shown in Table 1. For example, type 1 locations are targeted as wetlands by all three source data bases while type 6 locations are identified as wetlands only by the ONC inundation data base.

Table 1. ISRC: Data Sources For Wetland Locations

| Tape | M&F ¹ | Data Source Combinations |
|------|------------------|--------------------------|
| 1 | A | UNESCO + FAO + ONC |
| 2 | B | UNESCO + ONC |
| 3 | C | UNESCO + FAO |
| 4 | D | UNESCO |
| 5 | E | ONC + FAO |
| 6 | F | ONC |
| 7 | G | FAO |
| 0 | | other (non-wet) land |
| -1 | | water |

¹ letter reference from Figure 5 of Matthews and Fung (1987)

Section 2. WETLAND TYPE

Description: IWET

A total of twelve wetland types are identified in the array IWET. Twenty-eight wetland vegetation types were originally chosen from the UNESCO system and classified into five major wetland groups on the basis of vegetational features and environmental characteristics that affect methane emission (as discussed in Matthews and Fung 1987); these are: (1) forested bog, (2) nonforested bog, (3) forested swamp, (4) nonforested swamp and (5) alluvial formations (see Table 2). Many additional locations identified as wetlands from the FAO and ONC data bases were occupied by about 100 vegetation types other than these 28 explicit wetland ecosystems. For the calculation of methane emission, vegetation types in these additional cells were initially grouped into seven categories on the basis of climate and vegetational structure (6A through 6G under G1, Table 2); each category was then associated with one of the five major wetland groups. Column G2 (Table 2) shows the secondary groupings of the additional seven vegetation categories with five major wetland groups. To allow for alternative combinations, all twelve wetland types are identified separately in the archived data base, as indicated in the Tape column.

Table 2. IWET: Wetland Types and Wetland Groupings

| Tape | G1 ¹ | G2 ² | Description |
|------|-----------------|-----------------|--|
| 1 | 1 | 1 | forested bog |
| 2 | 2 | 2 | nonforested bog |
| 3 | 3 | 3 | forested swamp |
| 4 | 4 | 4 | nonforested swamp |
| 5 | 5 | 5 | alluvial formations |
| 6 | 6A | 3 | tropical/subtropical forest/woodland |
| 7 | 6B | 3 | temperate forest/woodland |
| 8 | 6C | 1 | high-latitude temperate/boreal forest/woodland/shrub |
| 9 | 6D | 3 | shrubland; xeromorphic formations; desert |
| 10 | 6E | 4 | wooded grassland |
| 11 | 6F | 4 | nonwooded grassland |
| 12 | 6G | 2 | tundra |
| 0 | | | other (non-wet) land |
| -1 | | | water |

¹ type number from Table 2b and Table 5 in Matthews and Fung (1987)

² wetland group with which type was associated for methane emission calculation (Matthews and Fung, 1987)

Section 3. FRACTIONAL INUNDATION

Description: FRIN

The fractional inundation data base (FRIN) was compiled from a series of 1:1M scale Operational Navigation Charts (ONC). The values, which give the inundated proportion of 10^6 cells, were used to calculate the global wetland area of $5263 \times 10^9 \text{m}^2$ (Matthews and Fung, 1987). For cells targeted as wetlands by UNESCO vegetation or FAO ponding but not by the ONC inundation data base (i.e., cases 3, 4 and 7 in Table 1), the fractional wetland coverage was prescribed as the mean inundation for the vegetation type occupying the cell; these locations were incorporated into the fractional inundation data base.

Table 3. FRIN: Fractional Inundation

Section 5. SOIL TYPE

Description: ISOL

Soil types for wetland sites (ISOL) are from the data of Zobler (1986), digitized from the global series of soil maps produced by FAO (1971–1981). Locations are identified by integers associated with 106 soil units; ice is identified as 107. Table 5 lists integer values on the tape, along with FAO codes and FAO soil unit names. Note that FAO soil unit data in this array are independent of the distribution of ponded phase soils (from Zobler 1986) selected as one of three sources used to identify wetland locations by Matthews and Fung (1987).

SECTION 6. METHANE EMISSION FROM NATURAL WETLANDS

The data bases presented here were developed to determine the distribution and characteristics of natural wetlands on a global scale and to evaluate the role of wetlands in the annual emission of methane from terrestrial sources. Table 6 (from Matthews and Fung, 1987) shows the latitudinal distribution of wetland areas and the annual methane emission from wetland groups (see Section 2 and Table 2 for explanation). The length of methane emission periods was derived from simple assumptions about the likely duration of thaw conditions in high latitudes and inundation conditions in the subtropics and tropics.

The latitudinal distribution of wetland area derived here shows approximately 50% of the world's wetlands, primarily peat-rich bogs, concentrated in the zone between 50°N and 70°N. Peat-poor swamps, with lower flux rates and longer methane production seasons, are prevalent in low latitudes; about one-third of the wetlands are spread throughout the area from 10°N to 30°S. In this study, the distribution of emission generally parallels that of areas since large daily flux rates for short seasons in the high latitudes balance lower fluxes for longer periods in the tropics and subtropics. The total annual emission of methane from natural wetlands was estimated to be ~110 Tg (10^{12} g), equal to about 20% of the total terrestrial source strength.

Wetlands are generally acknowledged to play a significant role in the global methane budget. The series of data sets presented here, integrated into a comprehensive data base of wetlands and their attributes, provides a framework to analyze and evaluate the role of wetlands in the methane cycle. However, estimates of the magnitude and seasonality of this source may be considered preliminary; further constraints on the wetland source will be provided by measurements in a greater variety of representative wetland ecosystems and throughout methane production seasons and by isotopic measurements.

| <p>16. Abstract Global digital data bases on the distribution and environmental characteristics of natural wetlands, compiled by Matthews and Fung (1987), have been archived for public use. These data bases were developed to evaluate the role of wetlands in the annual emission of methane from terrestrial sources. Five global 1° latitude by 1° longitude arrays are included on the archived tape. They are: (1) wetland data source, (2) wetland type, (3) fractional inundation, (4) vegetation type, and (5) soil type. The first three data bases on wetland locations were published by Matthews and Fung (1987). The last two arrays contain ancillary information about these wetland locations: vegetation type is from the data of Matthews (1983) and soil type from the data of Zobler (1986).</p> <p>Users should consult original publications for complete discussion of the data bases. This short paper is designed only to document the tape, and briefly explain the data sets and their initial application to estimating the annual emission of methane from natural wetlands. This memo includes information about array characteristics such as dimensions, read formats, record lengths, block sizes and value ranges, and descriptions and translation tables for the individual data bases.</p> | | | | | |
