AMERICAN PULPWOOD ASSOCIATION

Figure 1 — The 12 Southern States and the counties or parishes in each.

Introduction

This publication contains historical pulpwood production data derived from canvasses of wood-using pulp-mills that have drawn roundwood or wood residues from the 12 Southern States (fig. 1). These canvasses have been conducted annually for the last 41 years.

The pulpwood canvass data were compiled, analyzed, and reported on an alternating basis by personnel from the USDA Forest Service, Southern and Southeastern Forest Experiment Stations (now combined into the Southern Research Station). The canvasses were conducted to determine the amount and source of pulpwood receipts by county and to determine interstate and cross-regional movement of industrial roundwood.

Pulpwood production data is combined with the periodic canvasses of all other primary wood-using plants conducted in Southern States to complete the picture of total timber product output. This data complements the Forest Inventory and Analysis periodic inventory of volume, growth, and removals from each State's timberland. All production figures are reported in cords.

Pulpwood

Relatively stable economic conditions have prevailed over the last four decades, creating a nearly constant increased demand for pulpwood. The rise in population, combined with an increase in the per capita consumption of paper, paperboard, and other nonpaper products of pulpwood have been conducive to expansion throughout the industry and fueled the general upward trend in pulpwood production. Southern production has increased more than fourfold from 16.2 million cords in 1953 to 66.3 million cords in 1993 (table 1). Total pulpwood production for the last 40 years equals almost 1.8 billion cords harvested from Southern timberlands. If these cords were stacked end to end, the resulting 2.6 million miles of wood could circle the earth 106 times or go to the moon and return 5 times. Tables 2 and 3 display total production figures by the Southeastern and South Central regions and year.

Roundwood

Several significant trends have developed in the Southern pulpwood industry over the last 40 years. Softwood roundwood production has more than doubled from 14.1 million cords in 1953 to 30.1 million cords in 1993. However, softwood roundwood expressed as a percent of total production has declined dramatically over the same time period (fig. 2). In 1953, softwood roundwood supplied 87 percent of the total pulpwood production. By 1983, it made up only 45 percent of total production and has remained relatively stable over the last decade. The decline in

softwood roundwood as a percent of total wood used was offset by the trend toward greater utilization of wood residues and the abundant hardwood resources in the South.

Hardwood roundwood production has climbed from slightly less than 2.0 million cords in 1953 to more than 16.2 million cords in 1993. Production methods and techniques developed over the last 40 years have enabled the pulp industry to utilize greater quantities of hardwood. In 1953, hardwood roundwood furnished only 12 percent of total production, compared to nearly 25 percent in 1993.

Wood Residues

Mills reported receipts of two kinds: (1) roundwood and (2) wood residues. Wood residues are primarily chips produced as a byproduct. However, an unknown proportion of these chips were produced from roundwood received at a primary processor (i.e., sawmill or veneer mill) and subsequently chipped. Figure 2 illustrates the dramatic increase in the utilization of wood residues for pulpwood. In 1953, the proportion of wood residues used for pulpwood was almost negligible at less than 1 percent. Using wood residues for pulpwood increased from 76,000 cords in 1953 to more than 19.9 million cords in 1993. Wood residue use has remained relatively stable since the late 1970's and in 1993 accounted for 30 percent of total pulpwood production.

Mills and Pulping Capacity

In 1953, 61 Southern pulpmills were operating and drawing wood from the 12 Southern States (table 4). Mill construction proceeded at a feverish pace during the mid-and late 1950's and again during the late 1960's and early 1970's. During the 20-year period between 1953 and 1973, 50 new mills were constructed, more than tripling daily pulping capacity. The number of mills operating in the South peaked at 115 in 1979. Even though the number of mills declined to 102 in 1993, the average daily pulping capacity increased steadily through expansion and modernization projects at existing facilities. In 1953, the combined daily pulping capacity of Southern mills was 28,670 tons or an average of 470 tons per mill, about half the nation's total pulping capacity (Christopher and Nelson 1959). Combined daily pulping capacity in 1993 was 132,992 tons per day and averaged 1,304 tons per mill, more than two-thirds of the nation's total pulping capacity (Johnson and Howell 1996). Mills operating outside Southern borders but drawing some of their wood from the South have fluctuated between 4 and 15 mills.

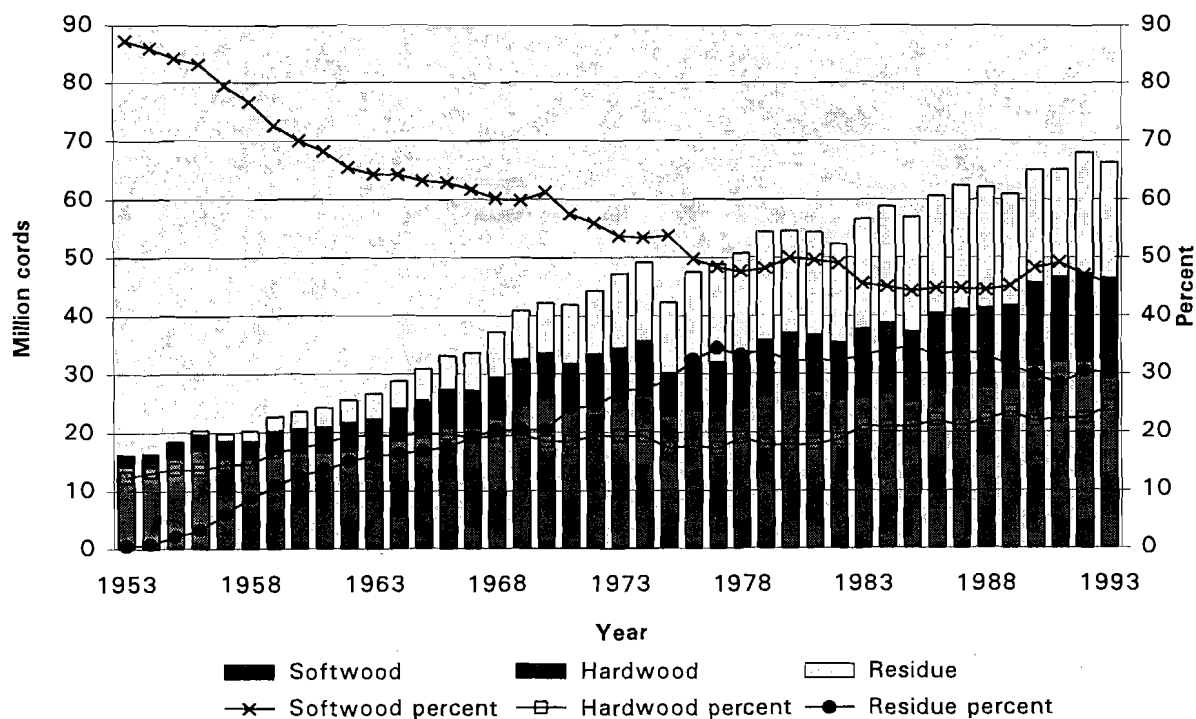

Figure 2—Pulpwood production in the South, 1953-1993.

Outlook

Over the last 40 years, pressures on the pulpwood supplier to reduce costs and increase production have vastly improved harvesting techniques. The traditional short-stick pulpwood harvest operations of the early 1950's have almost been replaced by totally mechanized tree-length harvesting operations. Mechanical tree harvesters and in-woods chipping operations have allowed almost total tree utilization in softwoods and hardwoods. Utilization of wood residues from primary processors is equally high. A recent timber products assessment for the Southeast (Johnson 1994) showed wood residue use at almost 100 percent.

The latest Forest and Rangeland Renewable Resources Act (RPA) projections of prospective demands for timber products show that the consumption of pulp, paper, and paperboard will continue to rise and may increase by as much as 50 percent by the year 2040 (Haynes and others 1995). By virtue of its tremendous pulping capacity, the Southern pulpwood industry will play a major role in supplying this increased demand. To meet future demand, a higher proportion of waste paper will be used as a fiber source. Waste paper use will probably reach 45 percent of fiber used in the manufacture of paper and paperboard by the year 2040 (Haynes and others 1995). Technical innovations have led to increased use of hardwoods and recycled waste paper, and the decline in using virgin fiber will probably occur almost solely in the softwood fiber source.

The Forest Service, U.S. Department of Agriculture, is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives—as directed by Congress—to provide increasingly greater service to a growing Nation.

The United States Department of Agriculture (USDA) prohibits discrimination in its programs on the basis of race, color, national origin, sex, religion, age, disability, political beliefs, and marital or familial status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means of communication of program information (braille, large print, audiotape, etc.) should contact the USDA office of Communications at (202) 720-2791. To file a complaint, write the Secretary of Agriculture, U.S. Department of Agriculture, Washington, DC 20250, or call (202) 720-7327 (voice) or (202) 720-1127 (TDD). USDA is an equal employment opportunity employer.

Johnson, Tony G. 1996. Trends in Southern pulpwood production, 1953-1993. Resour. Bull. SRS-3. Asheville, NC: U.S. Department of Agriculture, Forest Service, Southern Research Station. 18 p.

Southern pulpwood production has increased more than fourfold from 16.2 million cords in 1953 to 66.3 million cords in 1993. Softwood roundwood production more than doubled in the same time period; however, softwood production expressed as a proportion of the total production dramatically declined. In contrast, hardwood roundwood production and production from residues of all types substantially increased. The average daily pulping capacity of Southern mills climbed from 28,670 tons per day in 1953 to 132,992 tons per day in 1993. Southern mills accounted for more than two-thirds of the nation's total pulping capacity in 1993.

KEYWORDS: Pulpmills, pulpwood, roundwood, residues, pulping capacity.

Southern Research Station

Established 1921

The Southern Research Station, headquartered in Asheville, North Carolina, is one of the seven regional Stations and the Forest Products Laboratory that make up the Forest Service research organization.

RESEARCH MISSION:

To acquire the knowledge, develop the technology, and disseminate the research findings required to manage the Southern forest resources in ways that satisfy demands of goods and services while maintaining a quality environment.
